DISSECTING ANEURYSM OF THE AORTA AND PULMONARY ARTERY FOLLOWING RUP-TURE OF THE ARCH OF THE AORTA.*

By LAWRASON BROWN, M. D., Saranac Lake, N. Y.

This case is reported on account of the unusual course taken by the blood after rupture of the

The patient presented himself for examination October I, 1907, complaining of pulmonary tuberculosis. He was a male, fifty-four years of age, of small stature but wiry.

a male, fifty-four years of age, of small stature but wiry, and by profession a lawyer.

Family History: His father died at the age of eighty-six from apoplexy, mother died at seventy-three from chronic Bright's disease associated with arteriosclerosis, one sister died at sixty, apoplexy; one brother at fifty-one of Bright's disease. One sister died at childbirth.

Personal History: The patient, until the present illness Personal History: The patient, until the present lines, had always been well and strong. He was a hard and active worker with a large law practice. No note in regard to syphilis was obtained for the reason that the patient was always accompanied by his wife, except on one or two occasions when this point was overlooked. He was undoubtedly exposed in his early life. He used alcohol controlled the strong process of the strong patients.

stantly, but in moderation.

Present illness: The patient began to run down, lose weight and strength three or four years ago. After a trip weight and strength three or four years ago. After a trip to Atlantic City, however, he was greatly improved. He had had a slight hacking cough for eighteen years, which he had attributed in part to tobacco, which he had used freely. He had had some elevation of temperature at times for several months previously to coming to the Adirondacks, and for a few weeks the temperature had ranged from 99° to 703° F. During this acute attack cough and expectoration had increased, in which his physician found "tubercle bacilli." He also had night sweats, but no pleurisy, no shortness of breath, and no hæmoptysis. He had no pain in the throat nor hoarseness. His appetite was good

Status Præsens: October 1, 1907, 2 p. m. Weight 106 (normal 112), height 5 feet 23/4 inches, temperature 97° F., pulse 100, respirations 24. General condition poor. Slightly anæmic appearance. Radial arteries thickened, the examination of the heart, except for accentuation of the second

pulmonic sound, negative.

Lungs: Right: slight dulness to the third vetrebral spine, good vesicular murmur, fine râles to the clavicle and the third vertebral spine on cough. Left: the side much contracted, the vocal fremitus increased, some dulness over the entire back. The vocal resonance was increased. There was bronchovesicular breathing to the clavicle. Coarse rales were heard in the outer fourth and fifth interspaces, and from the sixth vertebral spine to the base. A few fine râles were present at the base in front.

The sputum was examined on three separate occasions and no tubercle bacilli were found. The urine was

From this time to December 4th the patient was seen frequently and gained ten pounds. His temperature was

95° or 97° F., his pulse 100 to 108, his respirations 26 to 30. December 1st the patient spat blood several times. The actual source of the blood was not determined, but about actual source of the blood was not determined, but about this time the patient spent two days in bed with slightly elevated temperature, and while in bed spat blood once. He alco complained of a little pain in the right lower chest. On January 16th the patient had an attack of phlebitis in On January 16th the patient had an attack of phlebitis in the left leg, which was swollen, painful, and ordematous. Under rest, in bed, ice bag, bandaging, and massage he made a good recovery. He steadily improved and when examined on February 11th it was noted that possibly there were a few fine râles above the right clavicle. On the left there was the slightest dulness, and the breathing was slightly distant on the back. There were a few fine râles at the very base on cough. At this time the patient weighed six pounds more than his previous maximum.

On February 17, 1008 about 8 a m while the patient

weighed six pounds more than his previous maximum. On February 17, 1008, about 8 a. m., while the patient was eating his breakfast, he felt a sharp pain at the base of his neck and fell off his chair, but recovered himself, sat down again, and then fell forward unconscious on the floor. Up to this attack the patient had been feeling very well; only a few days before he had been dancing with a chair about the parler of his hotel, and said that he had not felt so well for a long time. He remained unconscious for about one half hour, and then gradually regained consciousness and vomited his breakfast and other fluid in large quantities, a quart at a time. During this period of sciousness and vomited his breakfast and other fluid in large quantities, a quart at a time. During this period of unconsciousness the patient had an involuntary movement of the bowels. While the sounds of the heart could not be heard the pulse could be felt, but was considerably weaker on the right side. The patient gradually recovered but was kept in bed, though he did not see why he should have to stay there. When seen about 6 p. m. he was lying in bed on his right side, but experienced no difficulty when he turned on his left. He looked well, his color was good, no cyanosis present. There were bruises on his forehead and on the top of his head from his fall. The left pupil was somewhat larger than the right; both reacted to light and accommodation. There was no sign of paralysis of the face or rest of the body, nor had there been at any time. The right jugular was considerably more prominent than the right jugular was considerably more prominent than the left. The pulse in the right wrist was weaker than in the left, but was weak on both sides; thickening of the arteries had been noticed. The temperature was normal, and the pulse was not rapid.

pulse was not rapid. Examination of the lungs showed the breathing was harsher on the right, with slightly increased vocal resonance over the front. The back was not examined. Heart: As the light was poor the visible pulsation was not looked for, but the pulsation was felt both to the right.

not looked for, but the pulsation was felt both to the right and left of the sternium, but very weak. There was no thrill. On percussion the dulness extended about midway between the sternal border and the nipple line on the right and to the same distance on the left. The sounds were clear, not accentuated nor loud, but heard just as loud, if not lounder, on the right than on the left.

Both the plantar and the knee reflexes were normal. The grip in the patient's right hand was weaker than in the left.

From this time on the patient rested comfortably until about 1:30 a. m. (February 18th), when he had severe dyspnæa, his eyes rolled toward the left, he complained of a burning in his throat, clutched at his throat, and tried to get out of bed. He was restrained, and in a few moments, while conscious, died. No pulse could be felt during the

'Read before the American Climatological Association

Post mortem examination was made at 10 a, m. Body of well nourished man. Several bruises on head. Slight hypostatic congestion of the skin on back. Well marked rigor mortis. Muscles normal in color. Panniculus fair thickness.

On opening the abdomen the bowels were slightly distended, but otherwise normal. Peritonæum normal. The cartilages were partly ossified. The heart was found to lie largely under the sternum, and about the heart was a clot

Fig. 1.—Anterior view of heart, showing greatly enlarged aorta and blood about pulmonary artery.

of blood from three to six or seven millmetres in thickness. The patient had been embalmed before the autopsy and the blood in the pericardium had apparently been partly coagulated by the embalming fluid. The aorta was considerably enlarged and very black in appearance. The pulmonary artery was much smaller, but also ance. The pulmonary artery was much smaller, but also very black. On opening the aorta, at a distance of 2.5 cm. above the aortic valve and on the lesser curvature was found a semilunar rent (with the upper semicircular flap well curved away from the heart) of the intima and media. The greatest distance between these two flaps was I cm. This was covered in part by a thrombus. The blood had dissected away the adventitia to the base of the heart on both aorta and pulmonary artery and it extended in the opposite direction along the pulmonary artery a considerable distance into the lungs, so that on separating the lobes of the right lung the extravasated blood could readily be seen under the pleura about the base. It also extended into the left lung, but to a lesser extent. Along the aorta it extended beyond the first or second pair of intercostal arteries. The thickest portion was opposite the rent and on the side of the arch near the pulmonary artery, which was much narrowed by the extravasated blood. A small ulcerated area was seen over this portion, where the blood had probably leaked into the pericardium. The heart was found firmly contracted, both auricle and ventricle, and contained very little blood (due possibly to the embalming contained very little blood (due possibly to the embalming process). The valves were somewhat thickened but apparently functioned perfectly. On the endocardium were seen several yellow patches of atheroma. The aorta contained a number of atheromatous patches, and in the transverse portion of the arch there was one small puckered area which somewhat suggested a sear, and several of these areas were seen in the descending aorta. The vessels

from the arch were the right innominate and the left common carotid, the left subclavian and the left vertebral. The rent extended diagonally across the arch, ending at the opening of the left common carotid. The heart was considerably hypertrophied. The coronary vessels showed marked tortuosity and atheromatous changes, but no embolus. The lungs presented a few adhesions at the left base and the anterior edge of the right middle lobe. They were comparatively free from blood and contained besides slight puckering at the apices little or no evidence of tuberculosis.

The liver was somewhat enlarged. The spleen was was slightly enlarged. The kidneys were normal except for a sear left by an old infarct on the right. The brain was not examined. The left iliac vessels were normal, and

Anatomical Diagnosis: Dissecting aneurysm of the transverse portion of the aorta with rupture into the pericardium. A marked arterial degeneration of the aorta.

Through the kindness of Dr. Samuel M. Brickner, Dr. F. S.

Through the kindness of Dr. Samuel M. Brickner, Dr. F. S. Mandelbaum examined microscopically specimens from the liver, aorta, and puckered area in the lung. "The aorta showed a chronic endarteritis with fatty changes and ulceration—the usual picture in such cases—and the liver showed chronic congestion with secondary atrophy of the liver cells. There was nothing pointing to lues." The lung showed no tuberculous changes.

Among the points of interest in this case is the observation of tubercle bacilli in the sputum by the physician who attended him during his acute aftack, probably a nontuberculous bronchopneumonia

I A period new of reacts and at through media and account and blood clot between media and adventura. The entropy is readily seen.

which cleared up rapidly after his arrival in the Adirondacks. The patient had no evidence of any tuberculous lesion in the lungs. Another point of interest is the fact that the usual course of the blood along the thoracic and abdominal aorta was probably interfered with by the scars previously mentioned. This probably forced the blood toward the

heart and along the pulmonary artery. Why it pursued this course instead of following the vessels of the neck is difficult to state. It is difficult also to explain the first period of unconsciousness, and the immediate cause of death was not determined, as the amount of blood in the pericardium was not large. Owing to the short time in which the

Fig. 3.—Right lung, showing blood lying along arterial vessels and under pleura.

autopsy had to be made it was impossible to open the brain, and the thoracic organs were removed in toto. Shortly after the period of unconsciousness, the physician who was called in in the emergency made a diagnosis from the large quantity of fluid vomited of acute dilatation of the stomach. Later in the day, when the patient was very much improved, it was readily seen that the heart dulness was displaced and there was pressure upon the arch. Aneuryism was suggested, but on account of the recent phlebitis a diagnosis of embolism of one of the large vessels of the lung seemed most probable.

THE RELATION OF LOCOMOTOR ATAXIA AND PARESIS.*

By J. RAMSAY HUNT, M. D.,

New York,
Chief of the Neurological China (vol. Inserticus in Netvous Inseases in the Consul University Medical College, Neurologist to the City and the Eabus- Hospitals

In the whole chapter of locomotor ataxia there is no question of greater importance than the relation which this affection bears to the general

*Discussion on Locomotor Maxia, it the meeting of the Medical Association of the Greater City of New York, Merch 19, 19-8.

paralysis of the insane. The importance of this relation is not merely a clinical one, but has a much deeper significance as bearing upon the underlying nature and ætiology of the two diseases. In the present communication there will be no discussion of the symptomatology of tabes or of paresis. My remarks will be confined to the combinations of the two diseases and the nature and significance of the so called "taboparesis." When they occur together is it to be regarded as a mere coincidence or complication, or are the two affections essentially the same in nature, differing only in their localization?

As is well known, tabes dorsalis is a disease characterized by degenerative changes in the posterior roots and posterior columns of the spinal cord. An antecedent syphilis is now generally regarded as the essential ætiological factor in the production of this degeneration (variously estimated from fifty to ninety per cent. of the cases). This is not syphilis in the ordinary acceptation of the term; but presumably a toxic state following in its wake, the so

called parasyphilis or metasyphilis.

Paresis, on the other hand, is a degenerative affection of the cerebral cortex, a degeneration of the association and projection neurones of the brain. It bears the same ætiological relation to antecedent syphilis as does tabes (according to Mendel occurring in seventy-five per cent. of the cases). This relation to syphilis constitutes an important bond of union between these two affections, which are so frequently found associated. Indeed, so close has this relation appeared to Moebius that he has termed paresis the "tabes of the brain," and no less an authority than Fournier has said of tabes that it is not an affection of the spinal cord alone, but one of the cerebrospinal axis.

The Combination Form of Tabes and Paresis (Taboparesis).-The clinical course of events in the development of taboparesis may be as follows: Symptoms of locomotor ataxia may appear first, this affection running its usual course, the symptoms of paresis supervening. Such paretic indications may develop within a few months, or may not appear until after the lapse of many years. In rare instances as long a period as twenty years has elapsed between the onset of the tabes and the first symptoms of dementia paralytica. On the other hand, the case may begin as one of paresis, the tabetic symptoms developing subsequently. In not a few of the cases paresis and tabes begin simultaneously and run their course together. The importance of tabetic degenerations in the course of general paresis was first pointed out by Westphal in 1860. This combination, the taboparesis, occurs so frequently that it cannot be regarded as an accidental one, or as a mere coincidence. Nageotte found that two thirds of his cases of paresis presented symptoms of locomotor ataxia. Shaffer found the same complication in three fourths of his cases. Binswanger, who is somewhat stricter in his interpretation of what constitutes a tabes occurring in the course of paresis, records the complication in one fifth of his cases. I would emphasize the fact that these statistics are not based upon tabetics who were attacked with paresis, but refer to cases of paresis in which symptoms of locomotor ataxia are present. The proportion of cases of tabetics developing paresis is certainly very much In the clinic for nervous diseases of the Cornell University Medical College, under the direction of Professor C. L. Dana, there have been treated during the past six years 164 cases of locomotor ataxia; of this number sixteen only presented the mental or

somatic symptoms of general paresis.

Clinical Types of Taboparesis.—In order to show the numerous varieties and manifold clinical combinations which may be presented by the union of tabes and paresis, I will mention a series of clinical groups as outlined by Nageotte. It will be seen that these furnish nearly every possible transition and combination, from the simple uncomplicated tabes to uncomplicated paresis. Simple tabes; tabes with slight psychical disturbances; tabes with signs of incipient paresis; tabes with well marked paresis; paresis coming on early in tabes; paresis beginning with tabetic symptoms; tabes and paresis in combination; paresis in which the tabes appears late; paresis with only certain tabetic symptoms; paresis without tabetic complications.

The Pathology of Taboparesis.—The pathology of taboparesis has been the subject of much investigation and considerable controversy. It has been held by some that the spinal cord lesions in cases of taboparesis differ from those found in simple tabes. It is asserted that in taboparesis the endogenous degenerations are more numerous and occur more frequently than in true tabes, in which the characteristic root and root zone degenerations are found. While it is true that endogenous degenerations are more frequent in taboparesis, it must be admitted that they are also to be found in the uncomplicated tabes, and cannot therefore be regarded as constituting an essential point of difference. Some observers have also attempted to show that the cortical lesions of the taboparesis differ in their localization from those of true paresis, being distributed over the posterior and inferior convolutions of the brain rather than over the frontal and Rolandic areas, which is the favorite localization in true paresis. Subsequent investigation has also disproved this, and the tendency at the present time is to regard the cortical changes in both affections as essentially the Pathological evidence and opinion at the same. present time is in favor of regarding the lesions occurring in taboparesis and those occurring in simple tabes or uncomplicated paresis as kindred in nature.

I would here mention an interesting pathological change which is found in the cerebral cortex in some cases of locomotor ataxia, cases which presented no demonstrable mental symptoms during life. These cortical alterations are histologically similar to those found in paresis, only much milder in degree. The existence of such alterations in the cortex of tabetics as a further evidence of the intimate kinship existing between the two affections. Such findings may also be regarded as furnishing the anatomical basis for a group of tabetic cases which present very mild symptoms of mental change and deterioration. In such cases paresis may be said to be present, but in a slumbering state. As Dejerine has expressed it, there are many cases of tabes in which the general

paralysis remains silent.

Tocometer Attivia and Other Psychoses—In an affection so frequent and so widely spread as locomotor ataxia, it is not surprising that there are occa-

sionally found associated with it other forms of mental alienation, such as paranoia, manic depressive insanity, dementia præcox, and various mental states following drug addictions. These cases numerically are comparatively few, and it may be said that the overwhelming majority of cases developing serious mental symptoms fall into the group of de-

mentia paralytica.

A general idea as to the relation of tabes to insanity other than paresis may be obtained from the combined statistics of Siemerling and Moeli, who found among 12,800 insane sixty-one tabetics. It must also be emphasized that in the course of tabes, mild mental states may develop upon a neurasthenic basis, which are entirely curable, and respond readily to proper therapeutic measures. Such cases may be the cause of great anxiety from the resemblance which they bear to the early stages of paresis, the so called præparesis. This resemblance may be so close that the subsequent course of the case will alone furnish a satisfactory solution of the question. It is also well to recall in this relation the mild cortical changes found in some cases of simple tabes without appreciable mental changes, the silent or slumbering

In conclusion, it may be said that tabes dorsalis, dementia paralytica, and the combined form of the two affections, all have the common ætiological factor of an antecedent syphilis. The pathological alterations in the cerebral cortex and the spinal cord are essentially the same in both the isolated and the combined forms. The clinical combination of tabes and paresis are so varied and so numerous that a gradual transition may be traced from locomotor ataxia, on the one hand, to general paralysis of the insane on the other. In fact, it may be said that the more our knowledge of these parasyphilitic affections of the brain and spinal cord increases the more significant appears their combination, and the stronger becomes the tendency to regard them all as essentially of the same nature and origin.

112 WEST FIFTY-FIFTH STREET.

GLIOMA OF THE BRAIN. Operation, Death, Autopsy.

BY EDWARD E. MAYER, A. M., M. D., Pittsburgh,

Neurologisc, Presbyterian and South Side Hospitals, Associate Professor of Mental and Netwers Diseases, Western University of Pennsylvania, etc.,

AND FREDERICK PROESCHER, M. D.,
Pittsburgh,
Pathologist, Allegheny General Hospital.

The history given below, with the post mortem findings, presents enough interesting facts to render it worthy of extended comment:

Case December, 1000; Mrs. Del.a: age, twenty-nine years; married four years; one child, thirty months old; separated from husband. The medical history of ber family is exceedingly good, as was also her previous history, except for some of the usual children's diseases, which, however, left her unimpaired. She was brought up in affluence; her father failed, and shortly afterwards died, so that she was compelled at an early age to support her mother and the younger children by sewing. About four years ago, she was not sure that this was not in early pregnancy. For some

indefinite time, however, in after years she occasionally had recurrent attacks of a similar character. She also complained of several attacks of neuralgic pains on the

left side of her face during the last four years.

She was married four years ago to a man who shortly afterwards was sent to the penitentiary for fraud in his business, and who later went south on account of tuberculosis contracted in prison. Some two years ago she was treated by Dr. A. Wray Barcley, her family physician, for an intense pain in the back of her head, accompanied by fever which he considered to be meningitis. Since then she had pains in back of head repeatedly. She also gave a history of two recent attacks consisting of a sudden jerking of her left arm, twitching of her face and turning of her head to one side (she did not know to which side, nor did her mother), accompanied by a choking sensation like a ball in her throat, but without unconsciousness. was followed by her becoming rigid and remaining so for some time. Her first attack was on Hallowe'en, 1906, the second just before she came to me. She described the second one to me as a weak spell in which her arm became numb, but after she talked it became normal in feeling She had had repeated spells like this one, she told me, and her arm was getting weak from them, though I could not find objective evidence of it in grip, lifting power, or action of individual muscles. She had never been happy since marriage and would spend her nights crying and be moaning her lot, and her days working as expert seamstress to support herself and child. She had a very deep sense of honor and felt her husband's shame so much that she would not seek any companionship or friends. She was very high strung and irritable. Digestion was bad, and very night strung and irritable. Digestion was bad, and patient had lost about nine pounds in weight since the attacks began. Urine examination: No albumin, or sugar, sp. gr. 1.020, no casts. Blood: Red blood corpuscles, 5,020,000; white, 6,200; hæmoglobin, 85 per cent; blood pressure, 130. Reflexes: (tendon) slightly exaggerated, though equally so on both sides. Corneal reflexes had been lost. There was no objective evidence of motor weakness, despite her complaint of weakness of left side. No evidence of sensory disturbance, except that she seemed slow, though not exactly uncertain in the use of her left arm. She was seen several times in the next month, but nothing further was elicited.

May 6th. Ophthalmoscopic examination made, but fundi were found to be normal. No paralysis of ocular muscles. No heminaopsia. She complained, however, of weakness of sight, stating that she had a misty feeling before her eyes. She was not seen for several months, when, on August 17th, she came to me and reported a spell on the August 17th, she came to me and reported a speri of the street while going to church, in which she rolled down to the ground, jerked all over, and became cyanosed. She had to be assisted home. Since this attack her left arm had been twitching and her left leg felt stiff and weak. She was sent to the hospital for observation. The results of was sent to the hospital for observation. The rest our examination there now revealed the following:

Left Arm.—Slightly spastic. It often drew up in flexed

Left Arm.—Slightly spastic. It often drew up in flexed position with forearm pronated and adducted and with fingers flexed in hand. The deep reflexes of this arm were very much increased. Clonus was present, the slightest pulling of the fingers bringing it out.

Left Leg.—Slightly spastic, pulling the legs up with hands under the knees requiring more strength with this leg than the other. Babinski's sign present at times, though not constant. Ankle clonus present but not persistent. Cardon's reflex also Oncephein's, present at Gordon's reflex, also Oppenheim's, present at Percussion of end of last phalanx of small toe caused abduction of the foot with eversion. Deep pressure on inner thigh caused an extension of big toe. A similar pressure on right side produced an extension of the big toe of left foot, not as pronounced and not accompanied by flexion of the foot or by a movement of small toes. Even when done on the right leg, the extension of the left toe persisted for ten to fifteen seconds, and on some attempts the extension was even more marked than when tried on the left thigh. Deep stroking of inner part of lower leg (along tibia) evoked this same phenomenon when done on right leg (extension of left big toe), but not when tried on left leg (paradoxical sign). This phenomenon was always present even on days when Gordon's reflexes could not be elicited.

Abdominal skin reflexes were increased on left side, also cremasteric and genital reflexes.

Hand grip only 20 Kg. in left hand; 65 in right. No muscular wasting anywhere. Loss of body weight about 14

Sensory Symptoms.—Tactile sense decreased over fingers and knuckles of left hand. Slightly over left arm, left side of arm, left leg and foot.

Temperature Sense.—This was somewhat lessened and

delayed over left arm, hand, and left side of body.

Pain sense was normal.

Muscle sense was distinctly lessened in left hand. Stereognosis was lost in left hand. A piece of money was

not recognized or felt as such, nor was a knife, except at a third attempt. Patient could not distinguish the point from the head of a pin, etc. Localization by Volkmann test was imperfect also.

Bone conduction was delayed and in some attempts vibrations not appreciated on tibia and radial bones of left

Gait and Station.-On walking there appeared some tendency to go to the left. Station with feet together and eyes closed was uncertain, but it was questionable whether it was not due to weakness of the left leg rather than to inco-ordination. There was some ataxia of the left arm partially obscured by clonus and weakness of this arm. Movements of this arm were slowly executed and wrong things done by it, exasperating the patient, who continually told me she knew what I wanted her to do, but she just must, it seemed, do the wrong thing. For instance, I would have her stroke her hair, but she would stroke her forehead in-stead. Whether this could be called a true apraxia I could hardly say; it seemed to me more a muscle sense im-pairment associated with the asteriognosis. The paralysis of left arm and leg was growing daily more pronounced.

Vision.—Corneal reflexes were lost, iritic reflexes active. Optic neuritis in both eyes (Dr. E. B. Heckel was kind enough to ophthalmoscope her. No nystagmus or paresis of ocular muscles. No hemianopsia or other limitation of

Hearing, taste, and smell normal; speech normal; mind clear and active. Temperature range (observation three weeks), 98° F. to 99.8° F. Pulse, 64 to 104. Respira-tion, 16 to 24. The high records were upon admis-sion and normal conditions resulted from regulation of diet and rest, except for one day after withdrawal of stomach contents for analysis.

There was no question now of our patient having a brain tumor. Reasoning backward one could see that her tonic attacks without unconsciousness were epileptiform and similar to what is often noticed early in cases of brain tumor, and also that the lost corneal reflexes were similar to what is sometimes found, a congenital or normal condition with this patient, but at the time I first examined her her history made me think of nothing but hysteria. As is so often the case, no characteristic headache, nausea, or vomiting had occurred, but the coming on of localized motor and sensory symptoms, the presence now of optic neuritis and the steady and rapid progressiveness of the symptoms were sufficient indications of the presence of a neoplasm.

An operation was asked for, and, consent having been given, Dr. O. C. Gaub was asked to expose the parietal and postcentral convolutions. I requested pose the parietal and postcentral convolutions. I requested him to keep the inner interparietal sulcus in the centre of the field of operation. The operation was performed on the 15th of September. The skull was unusually thick and the drills used broke, so that the osteoplastic flap was completed by DeVilbliss rongeur, mallet, and chisel. Before the flap was completed the bleeding from the bone was free. The dura did not bulge and was divided when a sourt of blood ensued which imand was divided when a spurt of blood ensued, which immediately blanched the patient and stopped her radial pulsations. The operation was stopped, restoratives applied, the open area tamponed and bandaged, and the patient removed to her bed. Not having recovered consciousness the next day, the bandage was removed to relieve possible pressure, but the oozing was so great that pressure had to be lightly reapplied. Death occurred twenty-four hours afterwards.

Autopsy was held eight hours after death. It showed a gliomatous infiltration of the left brain comprising the precentral, postcentral, and parietal region, extending downward to the corpus callosum, and posteriorly invading a small portion of the occipital lobe. A secondary

growth was found on the right side in the posterior parietal region.

The accompanying pictures show the extent of the growth, the sections made being described in the autopsy protocol. The gyrus fornicatus is seen to be degenerated slightly in the third section, fully

Fig. 1.-Brain, showing glioma

in the sixth. The thalamus is intact, although distorted from pressure, and slightly striated in the third and fourth sections. In the sixth section the pyramidal tract is involved. The postcentral, precentral (slightly), parietal (except lower), and parietooccipital regions are involved on the right side, and the posterior parietal and a small occipital area on the left side. The area of pachymeningitis and the smeary, broken down brain substance in the outer cortical layers did not exist intra vitam, but resulted after the operation.

The symptoms of this patient present on the whole those which are now definitely accepted to indicate a lesion of the central and parietal regions. That this patient went for such a long time with only indefinite symptoms which were not conclusive of any organic disturbance, and then to practically suddenly show grave symptoms which could be seen to daily grow in intensity, is explainable by the

vented any operative success. But this post hoc reasoning was at the time certainly not conclusive enough to prevent an at least exploratory operation. Also the absence or slightness of the general signs of tumor or of pressure symptoms, taken in conjunction with the extensive symptoms developing floridly, would seem to indicate that the tumor was perhaps gliomatous or aneurysmal and therefore inoperable. But cysts (operable ones) could produce such a clinical picture, and, more than that, enucleable tumors have been operated on successfully where general symptoms were entirely wanting or vague. Localization is difficult enough without demanding of the neurologist that he accurately foretell operability and the nature of the growth that will be found in a given case. The hopelessness of other therapeutic measures will, even in very doubtful cases, demand that this last chance be offered to the patient, even though only one in every thirty cases can be successfully operated upon.

A large flap for operation is always indicated, because symptoms due to pressure of a growth can rarely be entirely eliminated, and also because the centres in the cortex are not always localizable under the same part of the skull because of the variation in topography of the sulci, which serve to demarcate the different areas. Schafer, as long ago as 1887, clearly pointed this out, and observers since then have noted the unreliability of the fissures as

Fig. 2 .- Section through glioma.

landmarks for functional centres. Galvanic stimulation after the skull is opened, with notation of the position of fissures, and convolutions is therefore

The 3 Transverse section of the Lore

growth beginning in the white matter and growing upwards to the cortex without for some time affecting any fibres of importance for function. That it was a gliomatous and nonenucleable tumor would in itself contraindicate operation, and its deep seat and extensive invasion would certainly have pre-

the only way to accurately determine the position of the motor centres.

The exact commencement of the patient's neoplasm cannot be ascertained from her history. Actional four or five years before her operation and death she suffered from gastric symptoms and nausea, a cerebral origin for them is not indicated by the history. Indeed, at no time did her gastric symptoms deviate from what might be expected to occur in ordinary indigestion. Her headaches also were never constant or intense or distinctly localized, except that she frequently complained of dulness in the back of the head, which, however, could just as well be considered as being neurotic in type, especially as her descriptions of it were vague. made one think of a paræsthesia rather than of an organic headache. Dizziness she practically never complained of. Optic neuritis only came on late in her history. The only general indications which she gave of the growth of a neoplasm were the convulsive attacks which she had and the subjective sensory changes which she complained of in her left hand. These sensory changes could have been due to an hysteric condition, which diagnosis, by reason of other details in her history, was first thought of. It was only after seeing her after her convulsive attack in August that the possibilities of a tumor were seriously considered, and that for this reason she was sent to the hospital.

That with such a widespread growth no signs of mental deterioration were noted is only explainable by the fact that the neoplasm was largely situated on the right side of the brain, though the mental acuity and logical faculties were remarkable in this young woman. The extent of the tumor posteriorly makes one wonder that no hemianopsia was found, though naturally the optic radiations could not have been damaged even by pressure. It is, of course, always posible for glioma to exist without disturbance in conduction, as the neuroglia takes no part in conduction. Indeed the growth seems to have exerted its pressure almost entirely laterally towards the opposite side, and even the motor symptoms were largely due to the destructive influences of the tumor invading this area from the mesal side

The peculiar nature of the reflexes I cannot explain satisfactorily. Commissural involvement certainly occurred, and this is, in the light of our knowledge concerning the nature of the tendon reflexes, the only reason we can give. To me it was very interesting to observe this persistency of reflex action in the left leg and foot when elicited from the right leg-at times more constant and more pronounced even than when tested on the left leg itself. The different clinical examinations not only showed that Gordon's and Oppenheim's signs are distinct and different from Babinski's, but also that they themselves are subject to peculiar variations. I can only regret that we were unable to make serial preparations and to trace the fibres in the various tracts, though probably this would not have resulted in furnishing us with any more definite conclusions.

I repeat again that the progressive development of symptoms was very rapid in the last few weeks of this patient's life, due, I suppose, to the tumor at this time having reached cortical areas. Her feeling of numbness on the left side, with weakness followed by ataxic movements, with the later development of distinct objective hyperæsthesia for touch, temperature, and pain on this side, accompanied by impairment of muscle sense and astereognosis, clearly indicated a destruction of that

part of the brain whose function dealt with sensation. To this was added the paresis of the left leg and paralysis of the left arm, which indicated involvement of the arm and leg centre of the right side of the brain. Indeed this paralysis existed to the extent of being accompanied with active contractures and clonus particularly pronounced in the left arm.

The location in a general way of the tumor, therefore, in this case was not difficult, as the symptons definitely indicated disturbance of the parietal and central region. This case, however, affords no assistance in determining some of the mooted questions of localization in this region, whether the motor area lies in the postcentral as well as in the precentral region, whether sensory and motor centres lie entirely separate and distinct, or are consensual, and whether asteriognosis is an ordinary sensation and located in the same areas as a simple sensation.

Histologically, Cajal and Flechsig, by two entire-

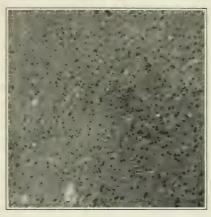

Fig. 4 —Microscopical section of the tumor. Low power, objective 4, ocular 4 (Zeitz).

ly different methods, and, anatomically, Brodman and Campbell have shown the differences between the precentral and the postcentral gyres, differences which lead us to assume various functions, even had they not been confirmed to a large extent by the physiological experiments of Mott, Tschermak, Sherrington, Exner, and others. The accepted fact of the function of one hemisphere, or at least of definite parts of the cortex being assumed by the opposite side of the brain, cannot be a clinical factor. Indeed, if allowed to have any weight, it would hinder attempts at localization intra vitam. Similar conclusions are at present to be made in considering the various ideas of the extent of inhibition or disturbed function with a definite lesion, that of Monakow concerning distant effects of a lesion with his conception of Schaltzellen or Goltz's theory. which is almost the opposite.

Déjerine believes that the precentral convolution originates motion, but also that the sensory tracts terminate here. In other words, he regards the sensory and motor region as coinciding. Others in-

sist that the motor region is not confined, as generally assumed, to the anterior central convolution, but extends into the parietal area (see Lewandowsky), though only to a slight degree. Mills and Oppenheim have especially shown that, for practical purposes, the motor and sensory areas can be considered separately, the latter being located in the limbic and parietal lobes, more exactly the gyrus fornicatus, quadrate lobule, and the parietal convolution.

No atrophy was present in this case. In one of Mill's cases of a superior parietal tumor, marked atrophy occurred, from which he assumed the presence of a cerebral trophic centre in the gyrus fornicatus, referring also to Savill's case in Brain, 1891,

as an added proof of such an assumption.

This patient corresponded in type to the characteristic cerebral sensory paralysis in that it extended to about the middle line and in that it was more marked in the distal parts of the extremities, a fact which, as Bonhoffer pointed out, refutes Munk's views concerning cerebral sensory localization.

It is impossible to enter here into the subject of stereognosis and what help it affords in localization. Prince, in his recent article, has discussed fully the complexity of sensations going to make up this condition and the absurdity to him of considering it as a "sense." There is a distinction between stereognostic perception and the recognition of objects by touch, although it is not always possible and not always necessary to distinguish between them and speak of primary agnosia, asymbolia, and tactile aphasia. Personally, I believe that the so called muscle sense and stereognosis are dependent upon the failure of the brain to register and to recognize sensory impressions, and that a wide area of brain is involved in defects of these "senses," agreeing in this way with the ideas of Prince. But I also believe that disturbances of this character are localizable postparietally, that this area is used for the interpretation of sensory registrations, forming a centre. In the patient whose history has just been cited there was pronounced diminution of tactual sensation and of tactile stereognosis on the left side, but no impairment on the right side. The autopsy showed extensive involvement of the postcentral and parietal region of the right brain, which is what was expected, but also a small tumor of the posterior parietal region in the left brain-an unexpected finding and one which gave no symptoms. There was no lesion in the area for common sensation and therefore can we infer that in this posterior parietal region, tactual sensations are recognized and interpretated, and to find astereognosis clinically we must have involvement of the centres for ordinary sensation, as well of the stereognostic centre?

Autopsy.—A horseshoe shaped wound covered with matted blood was found above the ear. Removing the sutures which held the cut surface together, the skull was seen to be sawed through in the same manner, though not severed on the irontal side. The dura, which had been severed on the frontal side. The dura, which had been opened, was covered with blood and brain debris, which upon removal showed a smeary, cheesy, bloody brain substance underneath. No cerebral bulging took place upon removing the skull cap. The diploe of the frontal bone were strongly developed; those of the parietal and occipital bones were not as markedly. The convex side of the bone flap was toward the left and the base toward the temporal

The dura mater presented no alterations. There was a little blood in the longitudinal sinus. After stripping off

the dura there was found on the right posterior frontal surface of the archnoid an area about the size of a dollar covered with a greenish yellow, smeary mass. pacchmeningitis.) Around the perietococipital sulcus was found a spot two centimetres in diameter, dark red in color. The gyri were flattened, and the brain substance was very soft and vascular. The base of the brain, the hypophysis, and the arteries were normal. The brain weighs 1,450 grammes.

In situ the brain showed the following: An area extending from the middle of the superior frontal gyrus to the knee of the central sulcus and to the first occipital gyrus and the lateral occipital sulcus was sunken in. The surto the posterior central gyrus and from here to the lateral

occipital sulcus was a smeary, cheesy mass.

Transverse sections showed the following: First section made three and one half centimetres from the convexity of the frontal lobe about the middle of the frontal sulcus. Cortical substance and white matter revealed no change macroscopically. Left frontal lobe was smaller than the right. The inner surface of the left frontal lobe was

slightly curved to the outside (from pressure).

Second section made about the superior and inferior precentral sulcus. The anterior and middle portions of the cortex showed no alterations. About thirteen millimetres above the corpus callosum was a greyish red area, five millimetres in diameter, not sharply distinguished, and of about the same consistency as the grey matter. The white matter of the right side was seven centimetres in diameter, four centimetres on the left side. The corpus callosum was slightly pushed below the ventricle; the lateral ventricle, shortened and widened, appeared as an acute angled triangle. The basal ganglia of the right side somewhat shortened and widened and pushed downwards.

Third section corresponding to the anterior half of the anterior central sulcus. The outer grey mantle normal. Middle portion softened. Inner portion was greyish red in color. White matter here was 4.5 cm. in diameter against 1.7 cm. on the left side. Lentiform nucleus was somewhat obscured in outline. Internal capsule

slightly striated.

Fourth section through anterior and posterior central gyri. Outer grey mantle was normal. Middle part was destroyed with slight loss of upper white part. The upper two thirds of the inner grey substance was greyish red in color with numerous punctate hæmorrhages. Lower third normal. Corpus callosum pushed downwards. White matter here was 5.7 cm. in diameter, and 2.7 cm. on the left side. Nucleus caudatus and lentiform was shortened. Internal capsule was normal.

Fifth section, upper knee of central gyrus. Outer mantle was normal. Middle portion softened. Inner two thirds of grey matter absent. Lower one third greyish red, and covered with punctate hæmorrhages. White matter 4.5 cm.

in diameter on right side, and 2.7 cm. on the left.

Sixth section. Transverse section corresponding to the upper knee of the central gyrus. Outer cortical substance well preserved. The superior and the inner two thirds almost entirely destroyed. In the inferior zone of this section was found a grey red hæmorrhagic focus I.4 cm. long and 7 mm. broad. White matter 4.5 cm. in diameter and only 2.5 cm. broad on left side. Corpus callosum normal. Right lateral ventricle compressed to a narrow fissure. Fornix, optic thalamus caudate nucleus, internal capsule, lentiform nucleus, and claustrum were normal.

Seventh section. Transverse section through superior parietal lobe. Outer grey cortical matter entirely destroyed and covered with a friable grey red bloody mass. A grey red focus in outer half af white matter. Middle and inner cortex entirely absent. One third of upper and inner white matter was also destroyed, irregularly ridged, and dotted with hæmorrhagic spots. In the centre of the white matter was a pale greyish red area, 13 mm. long and 3 mm. broad. The inner upper half of the corpus callosum was a greyish red friable mass, the upper third was also destroyed. In the left hemisphere there was a 5 mm. in length grevish red area directly over the corpus callosum.

The anterior portion of the pons cut through in this section was shoved to the left.

Eighth section. Transverse section through the posterior part of the superior parietal lobe. The upper and inner grey and the upper white matter destroyed. Surface changed to friable greyish red mass. Right posterior horn

smaller than normal. Opposite posterior angle of the posterior horn was a grey red stripe, 5 mm. by 2 mm. in size, just below the inner grey cortex. A greyish red marbled area of softer consistency than the brain around it was found in the left upper and inner grey extending to the inner and outer surface. Pons and cerebellum were

Transverse section, I cm. behind the paraoccipital sulcus Middle and inner grey mantle destroyed, except for a small area. Surface greyish red in color. An area of degeneration about the size of a pea was found in the inner grey In the left upper and inner part was found a greyish red area which reached from the previous transverse section to the crest of the right occipital lobe. In the white matter, a few scattered slightly greyish red foci. In the left side the degenerated part described in last section extended

to the cuneus. The cuneus and lobus lingualis are normal.

Microscopical Examination of Tumor of the Left Hemisphere Staned with Iron Hamatesytlom-Weigert and Van Gieson.—With low objective the centre of the degenerated focus was seen to consist for the most part of round or oblong cells, darkly stained and embedded in a thick mesh oblong cells, darkly stained and embedded in a thick mesin interspersed with numerous small bloodvessels and of a light reddish yellow color. The cells were arranged in a regular manner and at some places in small groups. The walls of, the thinly walled bloodvessels were of a rosy red color. This growth passed gradually into the normal brain substance and was characterized by numerous large and small ganglionic cells, as also by a fine intracellular substance, and a small amount of small, darkly colored cells, processing protocologies and proof in ploodyessels. poor in protoplasm and poor in bloodvessels.

With a higher objective these small oblong cells were comparatively free from protoplasm or contained only an outer zone of protoplasm.

The nuclear part of the cells consisted of chromatin ele-ments with small or large nucleoli lying at some places diffusely in the chromatin, so that the cells appeared a homogenous black. Some polynuclear leucocytes were also The fibres were a large, straight intermesh of homo-s structure. The interrelation between fibres and genous structure. cells could not be demonstrated. Some of the round cells resembled ganglion cells; mitosis could not be found. The large and small vessels consisting of a single or double layer of endothelium, surounded by a thin layer of connective tissue, showed no alterations. The small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are also showed in the small celled describe which gradually are small celled described as a small celled described and the small celled described are small celled described as a deposits which gradually passed into the normal brain substance were characterized by numerous large and small ganglion cells (rich in protoplasm and containing large nuclei and nucleoli). The intercellular substance was very fine and thick, and contained fewer of the darkly stained cells.

We understand by glioma a tumor which is formed from the specific basal substance of the cerebral nervous system, the neuroglia (Virchow), and which contains in addition a small amount of connective tissue and bloodvessels. Gliomata macroscopically are easily characterizable in that, in contradistinction to other tumors of the cerebral nervous system (metastatic carcinoma or primary sarcoma), they are not sharply circumscribed by a necrotic zone of brain substance, but gradually fade into the normal brain substance of the brain or spinal cord. If the gliomata are not hæmorrhagically infiltrated (this applies to glioma of the grey as well as of the white matter) they cannot be easily distinguished from normal brain substance. Only the slight softer consistency and the slight elevation above the surface indicate the presence of a pathological alteration. The gliomatous condition is found generally in the cortex, basal ganglion, nucleus caudatus and lenticularis, vermis, etc., and, notwithstanding extensive degeneration, the cortex of the parts involved may be intact. Sometimes we find gliomata sharply circumscribed, or lying free in the ventricles, which are of harder consistency. The color of a glioma is similar in most cases to the grey or white matter, yellowish white, grey, and somewhat more translucent than the cortex. If it is a very vascular glioma, the tumor is reddish in color. If regressive changes have occurred the tumor is dotted from pigmentation, reddish brown,

greyish red, or purple in color.

Gliomata never extend to the meninges of the cerebral nervous system; another characteristic distinguishing them from similar appearing tumors is their infiltrating growth. The tumor radiates in all directions from its origin. Stroebe found, especially in gliomata of the pons, this typical infiltrating form of growth, the nuclear elements, pontile, and pyramidal tracts undisturbed, though microscopically the ganglionic cell and nerve fibres were replaced by gliomatous tissue. This infiltrating growth makes it very difficult to delimit the extent of the neoplasm.

Gliomata grow very slowly, and if centres important to life are not involved, they may attain a very large size (as in this case). As a result of this slow growth the brain adapts itself to the altered pressure, and compressio cerebri comes on very slowly or not at all. The form of gliomata rich in cells which is wrongly called the sarcomatous type grows more rapidly and is not an infiltrating form, but forms in masses which injure the surrounding brain

Gliomata are highly vascular tumors. As a result of degeneration, expressed by fatty degeneration, nuclear destruction or a kind of ædematous or gelatinous softening, reducing the tumor to a soft, slimy mass or resulting cavity formation (cystic glioma) changes in the bloodvessel wall generally occur. Rupture may take place from increased pressure on a thinned vessel wall, or the vessel wall may also be so degenerated that its resistance is so weakened as to give way from the blood pressure. Extensive hæmorrhages may therefore occur, converting the entire brain area into an apoplectic focus, which upon superficial examination would be diagnosticated as such. A thorough microscopical examination of the tumor mass is necessary to ascertain its gliomatous nature (glioma apoplectiforme). Fatty metamorphosis of the parenchyma of the tumor is probably a secondary feature resulting from hyaline degeneration, or a result of nutritive changes as a result of obliteration of the vessel walls. We often find the adventitial cells of the vessels in a gliomatous growth proliferating and leading to obliteration of the lumen.

Microscopically the neuroglia consists of cells and fibres, the latter being connected to the former protoplasmic prolongations of the cells. This conception is disputed by Ranvier and Golgi, especially by Weigert, for instance. Weigert regards the glia fibres as being absolutely independent of the cell A protoplasm prolongation of the cellular fibres does occur; the glia fibres only go to the cells or radiate from them and pass over them, but never join them directly.

Weigert's conclusions, based upon many years of observations, were:

1. The neuroglia fibres, which were formerly regarded as prolongations of Deiter's cells, are not identical with the protoplasm of the cells, but chemically quite different structures.

2. The chemical difference does not increase as we go further from the cell body, but the distinction commences near the cell nucleus.

3. These are therefore not prolongations, but fibres differing in composition from the protoplasm.

Weigert's views marked an epoch, and a true connective substance of the central nervous system was thought to have been discovered. Many prominent neurohistologists accept these views of Weigert's. Most of the anatomists of the central nervous system, especially Pelazzi and Stroebe, opposed these views, and showed that the glia cells were directly connected with the glia fibres (Mallory's stain). Obersteiner, Reinke, Robertson, Brodman, and Nissl all wrote against Weigert's views. Held comes to the following conclusions:

I. Free glia fibres occur. 2. There are fibres which meet with a protoplasmic prolongation of a glia cell and become closed in. 3. Some glia fibres lie in the cell body. 4. Some bundles of glia fibres are held together and accompanied along their entire course by protoplasm. Held cannot therefore agree that the glia fibres are completely emancipated from the glia cells protoplasm, and that it is purely an

intercellular substance.

A definite conclusion concerning this question was not possible, because neither Golgi's silver impregnation method, nor the carmine stain, nor Weigert's glial stain, nor its modifications by Bevan-Lewis, Benda, Kultschifzky, Yamagiva, Morel, nor Mallory's stain were capable of staining differentially the protoplasmic body of the glia cells. Recently Eisath has discovered a method, a modification of Mallory's axis cylinder stain, which enables one to distinguish the protoplasmic body of the glia cells and to show their direct connection with the glial

Eisath finds that the glia cells, as Held described before him, are composed of a cell nucleus and a translucent protoplasm colored light blue, the cells either round in contour or irregular with protoplasmic prolongations, and, if fibres are present, sheathed by this protoplasm. The fibres are stained dark blue and arise from the cell periphery or from

its interior.

The results of Eisath form the key to a proper understanding of Golgi's and Weigert's contradictions. The difficulty lies in the staining methods and in finding the protoplasm of the glia cells, which had a roundlike form, or send out dendrites, which must not be confounded with Weigert's chemically differentiated fibres.

To recapitulate:

Golgi with weak impregnation did not stain the cell body at all, so that the cell protoplasm did not become visible, and with deep impregnation the entire cell protoplasm became black, so that the protoplasmic elements could not be distinguished from Weigert's fibres. He therefore came to the conclusion that cell body and prolongation were a histologic unit. Weigert, on the other hand, by his method carried distinction too far, and the glial protoplasm entirely escaped him. He therefore arrived at the false conclusion that glia fibres and glia nucleus were entirely different structures; he also made the error of denying the existence of protoplasmic glia at those places in the central nervous, system where it existed normally, and failed to find glia in large areas where it existed-for instance, in the lower layers of the cerebral cortex.

Stroebe, by using Mallory's stain, found a chemical difference between glia fibres and glia cells, but not definite separation of fibres and cell body. Held confirms this view, and found in the layers of the cortex glia cells with jagged protoplasmic dendrites. Golgi's and Weigert's contentions are now therefore decided as Held and Nissl assumed they would be. Weigert's opinion that the neuroglia fibres are not identical with the protoplasm, but different chemically, is true, but this chemical alteration does not occur gradually in the protoplasmic prolongations, but occurs in the cell body. The glia fibres are not different from the cell body, are not therefore an intercellular substance in the sense of Weigert, but the fibres are imbedded in the glia protoplasm and are therefore a part of the cell, as Golgi assumed.

Gliomata (after Lenhossek, astroma) consists, therefore, chiefly of glia cells possessing these prolongations. There is no special type of intercellular substance. That which in gliomatous tissue has been described as a hyaline matrix or fine fibrillary substance is probably the result of degeneration of fibres or section of the glia elements. When hardened and stained (Mallory or Weigert stains) the glia is seen to consist of a very thick matrix, fine or coarse fibres, and nuclei or cells which are arranged either regularly or in groups. The nuclei are mostly round, containing little protoplasm. The fibres radiate from the periphery (star celled glioma, Stroebe), or the cells are elongated and oval, with the fibres arising from both poles (spindle celled glioma, Stroebe). Between the cells and fibres is probably an intercellular fluid. Remnants of nerve fibres and nerve cells are often found between the glia elements, ganglionic cells with large nuclei and nucleoli (Borst, Pels-Leusden, Stroebe, Hamilton, Flexner).

Stroebe found such ganglion cells in all gliomata examined by him. We will discuss later the similar development of glia cells and ganglion cells (ependymal cells). Kolliker called attention to the fact that glia and ganglionic cells resemble each other markedly throughout the cerebral nervous

We therefore see that the microscopical structure of individual tumors varies. If we insist upon Weigert's definition of neuroglia cells without prolongations embedded in a fibrous matrix we find numerous fields which agree with it (glioma poor in cells). With Van Gieson's stain we find many radiate from the bloodvessels; more rarely a chain of cells (Pfeile cells) are found. Occasionally gliomata are formed from spider cells or astrocytes (astroma), in which the mesh of the prolongations from the astrocytes varies, as we described it, in addition to long and short radiating ones, monster glia cells being found. The relation between cells and mesh varies. Sometimes the cells are in excess, so that the tumor resembles a sarcoma, and falsely is called a gliosarcoma. Astrocytes with giant cells may prevail, or the cells may be poor in protoplasm, very abundant with the intercellular substance, sparingly present, or not present at all. It is difficult to distinguish the last type from sarcoma. The investigations of Stroebe present contradictions between the type of normal glia and astrocytic glioma. In the gliomata, which are almost entirely formed of glia cells, the chemical differences of the glia fibres as a result of their rapid growth is not completed, while in normal glia and some gliomata in which spindle cells are not present, the opposite occurs. The protoplasmic relations between the two produce a distinction.

Developmental defects cause the formation of gliomata, as is corroborated by the simultaneous presence of other malformations of the cerebral nervous system and spinal canal (spina bifida), as also their frequent occurrence in children. They probably arise from groups of undistinctive cellular material. Rindfleisch, who first gave utterance to this view, said: "When the brain and spinal cord are completed, a remnant of embryonal tissue remains which belongs to the neuroglia and from which gliomata arise."

Lenhossek believes that in the completed central nervous system there is found, in addition to the developed astrocytes, a remnant of unattached glia cells, not used in the embryonal development from which tumors arise. Though this hypothesis is satisfactory, it is not probable. Lenhossek assumes for glia growths resulting from chronic inflammations, like Weigert, a nuclear increase of the prolongations of the cells. Mitotic division of the glia cells is positive in such cases. Borst and Stroebe also found numerous mitoses in gliomata.

Glioma have been lately described in which nuclei of an epithelial nature, formed of cysts, or canals, were noticed (Kaufman). From the developmental history of the cerebral nervous system we know that their basal tissue is epithelial. This epithelial character is conserved in the ependymal epithelium of the ventricles. Tumors in the ventricles of a purely epithelial character are often mixed with gliosal elements. An interesting tumor of this character was described by Kaufman.

SEVENTH AVENUE AND LIBERTY STREET.

LIGHT IN THE TREATMENT OF DISEASE AS USED AT BOULDER LODGE SANATORIUM, FORT DODGE, IA.

By J. W. Kime, M. D., Fort Dodge, Ia.

It is now some seven years since I began my investigations with light as a therapeutic agent. The profession then looked askance at anything along this line. It was new and untried, hence was beyond the pale of professional propriety. Any one tampering with the question was more than likely to be suspected of "fakeism."

Thanks to the perseverance of Finsen, Röntgen, Curie, and other earnest investigators, the subject of light in its various forms and manifestations has now been placed upon an enduring basis. With the host of imitators now in the field, however, with lamps innumerable foisted upon the profession, with an abundance of sensational and commercial literature, it will still require a number of years and much patience to sift out the good from the bad, the useful from the merely commercial.

Our own work here has been along the line of developing the use of the sun's rays as a therapeutic agent; to ascertain, in so far as we might be able, the possibilities and the limitations of these

rays. Hence much time in the beginning was devoted to the properties of the various kinds of light as regards the colors or wave lengths of the various rays.

Since photography offers the best means of ascertaining many of these points we made many experiments intended to show the photographic effects of the rays of different lengths as indicated by the various colors of the spectral rays. The photographic, actinic rays of light pass readily through blue glass; they are almost wholly cut off by red. The other colors transmit a greater or less percentage of actinic light.

Arranging strips of glass of the seven primary colors in the order red, orange, yellow, green, blue, indigo, and violet—though there are but three primany colors, red, yellow, and blue—and adding a strip of plain glass and a corresponding open space with no glass at all, as shown in Fig. 1 and Fig. 2, we found the following to be true: In Fig. 1 ordinary printing out paper as used by photographers was placed under the frame containing the strips of glass referred to, and was laid in the sunshine as ordinarily done in printing in photography. The exposure to the light was continued until the open space was fully printed. The paper was then toned in the ordinary way, with the result as shown.

It will be seen that no appreciable actinic light passed through red, none is apparent in orange, perhaps ten per cent. in yellow, green drops back to about three per cent., while blue jumps suddenly to 100 per cent., as measured by the open space which contains no glass. The indigo, which was but a dark blue, drops back a little, perhaps to ninety per cent., while the violet measures just about fifty per cent. The open space where no glass intervened between the sun and the printing out paper is of course one hundred per cent., and plain glass is about the same. There is no apparent difference between the blue and the open space.

Fig. 2 is just the reverse of Fig. 1. It was printed from a negative made in the ordinary way, except that it was done without the aid of the camera, the light being instantaneously admitted and cut off through an opening in the wall, no glass intervening except the strips of colored glass in the frame, which was bound to the sensitized plate. It shows that no actinic light reached the sensitized plate through the red glass. One hundred per cent. passed through the blue, while the other strips gave about the same results as in Fig. 1.

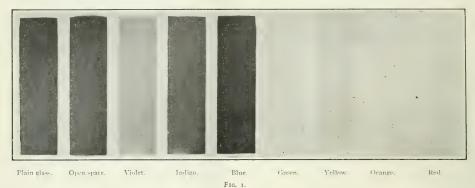

It will be seen that the photograph and the print exactly check each other, thus proving the value of the test. The violet perhaps serves as the best illustration of the completeness of the checking. In both the print and the negative the percentage of actinic light is the same, although the two processes were exactly the reverse of each other; that is, the percentage of light in the violet is just about fifty, thus accounting for the correspondence of the two results by opposite methods. The value of the blue ray from the standpoint of actinism is thus demonstrated. Red would be wholly useless from an actinic point of view.

Another property of the blue light is its coldness in comparison to white light. With the large condenser used at Boulder Lodge the reflected white light is so hot that it instantly sets fire to wood.

This same light, after passing through a single thickness of blue glass, is so cold that it can be used upon the bare body of the patient without discomfort. Since the strongest possible actinic light, as free as possible from heat, is desired, the blue light offers the best means of securing the strongest light for the treatment of disease. It is for this reason that we make use of the blue light, and the results here

patient. This reduces the heat to a very comfortable degree. It is necessary to cut the blue glass into narrow strips to provide for rapid expansion and contraction to avoid breakage.

The illustration (Fig. 3) shows the manner of using the light. The small disc standing near the nurse is three feet in diameter, and was formerly used in our work. The large disc is constructed

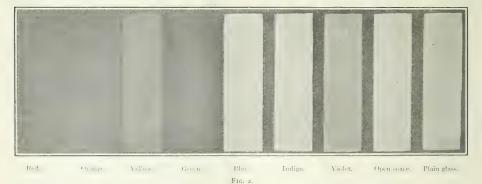

obtained are sufficient to warrant its continuance until something better has been demonstrated.

The very great inconvenience of obtaining the ultra violet rays and the comparative ease of obtaining the blue ray render the latter much more available for use.

Blue light, being a cold light and almost equally rich in actinic rays with white light, it has been our purpose to ascertain as nearly as possible the therapeutic effect of these rays.

upon the principle of a concave mirror. It weighs half a ton and is counterbalanced by a large weight. It is so mounted that it is readily made to follow the course of the sun through the sky.

Penetration of Light.—I am not unmindful that the penetrative power of sunlight has been denied. It has also been denied that the earth is round, that matter exists, and that an intelligent creative force lies behind the universe. We have, on the contrary, been able to demonstrate that the actinic rays of sun-

We have had constructed a very powerful condenser of sunlight. It is ten feet in diameter and is so made that all the sunlight falling upon its surface is reflected and focussed upon a point twenty feet in front of it. At this focal point a most intense light, accompanied by a corresponding heat, is concentrated. It instantly sets fire to any combustible material. A blue glass screen sixteen inches square is lung at the focal point, through which the light is passed before falling upon the bared body of the

light, even when unconcentrated, have very great penetrating power.

The following simple experiments were made with the kind cooperation of a number of my professional colleagues:

Small photographic negatives containing prints of various objects upon them were cut into sizes that would readily permit their insertion inside the mouth and against the inner surface of the cheek. The physicians wrote their names upon these negatives.

To the negatives small pieces of corresponding size to the sensitized plates were bound, and the pieces thus prepared were inserted into the mouths of the physicians, the negatives being placed against the inner side of the cheek and the sensitized plate resting against the outer surfaces of the teeth. Thus arranged in the photographer's dark room and with a black cloth over the mouth and nose and the mouth tightly closed to prevent the entrance of light the physicians stepped into the sunshine and for fifteen seconds held their cheeks toward the sun of a February day.

The reproductions of the views upon the negatives and the signatures of the physicians photographed through the thickness of their cheeks are conclusive that the chemic rays of ordinary sunshine have great penetrative power when permitted to fall It is usually denied that actinic light, or light of short wave length, will pass through glass. All my photographs here shown were taken through glass and through portions of or through the entire thickness of the body, and are quite conclusive that chemic rays do penetrate to great depth into the living tissues even after their passage through glass. Glass is no doubt opaque to the shortest rays of light, but it is perfectly penetrable to light rays rich in actinic power.

Therapy of Light.—We began our work as did Finsen and nearly all others who have worked along similar lines, with the idea that the light acted in a germicidal way, that the chemical rays in some manner destroyed the bacilli. It is well known that light inhibits the growth of many forms of pathogenic bacteria, and when sufficiently strong destroys

Fig. 3 - Manner of using sunlight.

upon the surface of the body. (Fig. 4.) The prints and signatures are: Bouquet of flowers, J. W. Kime; negative of man, Dr. H. G. Ristine; row of trees, Mr. Hostetler; man by train of cars, Dr. W. W. Bowen; boy on steps, Dr. W. R. Bates. I am under obligations to these physicians and to Mr. Hostetler for assistance kindly rendered.

In this connection I refer to my former experiments, in which I showed that concentrated sunlight penetrates through the entire thickness of the adult

thorax

Fig. 5 was made from a photograph taken in a manner quite similar to that described for the smaller photograph shown in Fig. 4. Here, however, the plates were placed upon the back, and the light was thrown upon the chest, the print being made by means of the light which had traversed the thickness of the thorax. (Medical Record, October 13, 1900.)

them, and it was believed that bacteria deluged with actinic light would lose their powers for doing harm. This in a measure is true, but in the light of experience we must look for additional reasons for the improvement manifested in these patients. While the light does inhibit the growth of bacill this is perhaps but one of the factors in the cure.

The effect of the light is at once apparent in the treatment of lupus and other chronic lesions of the skin in which there is an abrasion of the surface. Here, after a few minutes of application of the strong actinic light, the wound assumes an altogether different appearance. From a pale, ashy, lifeless color it becomes red, livid; the tissues become engorged with blood, the capillaries swell to the point of bursting, and drops of blood ooze from the surface and trickle over the edges. At the same time this light is comparatively cold.

To the irritating effect of the short rays we must:

look for the explanation of this turgescence, and it is without doubt in part due to the increased nutrition brought to the parts by the abundant flow of capillary blood that we must credit the favorable

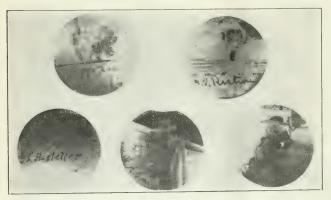

Fig. 4.-Penetration of light.

changes which occur. In these superficial lesions the bactericidal effect of the rays plays an important

In the deeper tissues, as the lung, capillary en-

In - Perst 2 and hight

gorgement likewise takes place, increased nutrition is brought to the affected areas, fibrosis is favored, and reparative processes occur which might not take place under less favorable circumstances.

Very material benefit is no doubt received by the patient in the bathing of all his blood in the powerful actinic light. During a treatment of twenty minutes' duration all the blood in his body passes

many times through the parts upon which the light is turned, and thus the direct results of the light are carried to the most remote portions of the organism.

Liebermeister says: "Light promotes the general power of assimilation. The more vigorously this goes on the greater will be the vital energy of the body and its power of resistance to everything injurious, especially to pathogenic microorganisms. This, as well as the hyperamia induced in the limbs exposed to irradiation for a long time, may explain the cures reported by Cicchansky, Poncet, Perdu, and Blanc in cases of local tuberculosis in joints and

We use the condensed blue light at Boulder Lodge in pulmonary tuberculosis, lupus, and other chronic skin lesions, and in postoperative surgical tuberculosis. In these affections light, and especially the shorter rays, is an agent of great utility.

In pulmonary tuberculosis the entire chest of the patient is made bare, and the light, after passing through the blue screen, is thrown directly upon the exposed portions of the body. These rays penetrate the entire thickness of the thorax, having a retarding influence upon the growth of bacteria and engorging the parts with blood. The light is used for twenty minutes each day. Our results since installing the large light have been so much better than before that there is no room for doubt as to the beneficial effect of these rays.

While by no means a specific, and in the far advanced cases of but little value, in early cases more rapid improvement is noted than was prior to the use of the light.

The psychic effect of the light is an adjuvant of no small consequence in cases of pulmonary tuber-culosis. If it had no other result whatever we would under no circumstances part with its use.

ANOTHER METHOD OF REGULATING PRESSURE IN THE BIER TREATMENT.

By Ralph Grace, M. D., New York,

Assistant Physician to the Lincoln Hospital.

I notice in the April 4th issue of the Journal of the American Medical Association, an article entitled An Accurate Method of Controlling the Pressure of the Bandage in Bier's Hyperamic Treatment, by Dr. Gordon Wilson, in which he recommends the Riva-Rocci sphygmomanometer.

I have been using recently in my practice a plan that seems to me much better in that it is more easily controlled and can be applied without special skill by anyone. It is by the hydrostatic sphygmomanometer devised by Dr. Louis Faugeres Bishop.

of New York.

To those not familiar with this instrument, I would say that it is an instrument for measuring blood pressure by a compression caused by a column of water of varying height. It consists essentially of two rubber bags connected by a tube; one being inside of the cuff and the other arranged for elevating and depressing. In the instrument is placed about twelve ounces of water without air. The ac-

The production of hyperæmia by means of the Bishop hydrostatic sphygmomerometer.

companying illustration shows clearly how the bandage is applied and how the pressure may be regulated by the patient. The cuff is laced to the part of the body that is to be compressed and the pressure regulated by elevating the reservoir bag. instrument also has many advantages for measuring blood pressure, which is indicated in millimetres of mercury on the tube and read at the level of the heart at the moment that the pulse disappears.

54 WEST FIFTY-FIFTH STREET.

BROKEN JAWS.

Citing Cases from Actual Practice: Causes, Symp. ... Diagnosis, Prognosis, Treatment.*

By DAVID B. FREUNDLICH, D. D. S., New York,

Dental Surgeon, St. Bartholomew's Hospital.

Fractures of the maxillæ occur quite frequently. They are usually the result of fist blows, kicks of horses, and are also very often caused by some heavy missile which has been thrown with great

Among other fractured jaw cases in my practice, there was one that was caused by a kick from a horse. On November 19, 1906, Dr. W. G., a veterinary surgeon for one of the largest express companies in this country, came to me for treatment. Upon taking the history of the case, I was informed that while in the act of administering some medicine to the animal he received a good, forceful kick, after which he lay unconscious for some minutes. While under my treatment he followed my directions religiously, and as the case progressed and improved, the result was all that could be hoped for. It was not before March 2, 1907, however, that I discharged the patient, pronouncing him perfectly well.

The following information will probably be of some interest to the members of the medical profession and its branches.

The superior maxillary bones are less frequently fractured than the inferior maxillary; and the reason for this is that the superior maxillary bones, on account of the location and shape, are less exposed to injury.

The inferior maxillary is more prone to fracture than any other bone of the face; and this is on account of its size, shape, and location. It might be of some assistance to us to know that the weakest point of the lower jaw is just anterior to the mental foramen.

Statistics tell us that fracture of the lower jaw is ten times more frequent in males than in females; and, personally, I am convinced of this statement when my mind reverts back to the time of previous election days in some of the "rough and tough" neighborhoods of this city. Broken jaws are "handed out" in a matter of fact fashion if the assailant so chooses, and if a blackjack isn't handy, brass knuckles will admirably answer the purpose. This is no fancy picture. I know it, because I have seen it during the time I was an employee of what was then considered the most corrupt city department in New York, and, I dare say, in the United States.

Fractures are divided into two general forms— simple and complicated. When there is no break in the continuity of the external tissues and when there is a single fracture of the bone, this is called a simple fracture. Complicated fractures include injuries to external tissues, vessels, nerves, teeth, to a comminuted condition of the bone itself, or any other condition which complicates a single fracture. We divide complicated fractures into multiple, comminuted, and compound.

When there is more than one break in the contin-

*Read before the Triprefessiona, Medical Sciency at New York, December 17, 1907.

uity of the bone we call it a multiple fracture, and under the heading of multiple fractures we include double and triple fractures.

When there is splintering and crushing of the bone into small fragments, as a result of crushing injuries or gunshot wounds, these are the comminuted fractures.

Where the fractured ends of the bone are exposed and the soft tissues injured, these are the compound fractures.

Fracture of the alveolar process is the most common fracture of the jaw, and it is generally associated with the extraction of teeth. These fractures do not involve any more of the process than the external plate lying right over the roots of the tooth extracted, and maybe a small part of the process adjacent to it. It might be interesting to know that fracture of the alveolar process is often the re-

Broken jaw, caused by a bloc view to claw with a blackjack

sult of a fall or a blow upon the chin, having an upward direction, driving the teeth into their sockets, and splitting the process on a line with the alveoli. Cases are on record where this has occurred to men engaged in the building trades as a result of a fall from a building and scaffolding. When this happens in the upper jaw, the external plate of the alveolar process is usually the part that gives way, as the palatal process supports the internal plate—hence its greater power of resistance. When the same accident occurs in the lower jaw, both the external and internal plates of the process usually fracture and separate.

As an aid to diagnosticate fracture of the lower jaw, it is well to be acquainted with the most frequent occurrences of fractures. Fracture of the lower jaw occurs most frequently as follows: I, Region of the cuspid tooth; 2, between cuspid and angle of jaw; 3, between symphysis and cuspid; 4, angle; 5, symphysis; 6, at points through ascending

ramus; 7, neck of condyle; 8, through coronoid process. Above the angle of the jaw fractures are exceedingly rare. Hamilton reported fifty-five cases of fracture of lower jaw, and only three of these were above the angle.

When injuries are received on the side of the face they usually result in fracture of the body of the jaw, through the cuspid, bicuspid, or molar regions, angle, or symphysis. When blows or falls are received upon the chin they usually result in fracture of the ascending ramus and neck of conductors.

A word about displacements. Where the fracture occurs at the symphysis the displacement is usually very slight; and this is because of the attachment of the muscles of the lateral halves of the jaw and their equalized action. It is important to know that this fracture may occur and not be recognized by the patient except from the crepitation produced when attempting to masticate food. When the fracture occurs at the neck of the condyle, the displacement as a rule is not very great. Of course there is a greater amount of displacement in multiple and

compound fractures than in simple fractures. In simple fractures through the cuspid region the displacement is not so great as when the same character of fracture is compounded into the mouth, because the covering tissues combat to a certain extent the tendency of the muscles to draw the ends of the fractured bone out of position. Where continuity of the covering tissues is broken there is full play of the muscles, and this causes a displacement which is in commensuration with the location and character of the injury.

The greatest amount of displacement is caused by multiple fractures.

Of course when displacement does occur it is then that the action of certain muscles is called into play, and it matters little to me what the names of these muscles are (as enumerated in textbooks), so long as I get a good look at the case, and treat the displacement, lacerations, etc., accordingly.

Allow me to say a word or two in regard to lines of fracture. The lines of fracture may be vertical, oblique, or horizontal. When the fracture is through the symphysis, it is always vertical. Fracture of the alveolar process is generally vertical and oblique combined, as can be seen when the external plate of the process is split off in the extraction of teeth or as a result of upward blows upon the chin. The great majority of fractures of the body of the bone, however, are oblique.

The thickness of the bone of the lower jaw is divided obliquely, so that generally the fracture occurs at the expense of the internal plate of the anterior portion and the external plate of the posterior portion. When the fracture is very oblique there is usually considerable overlapping and locking, making reduction sometimes very difficult.

Symptoms.—Symptoms of fracture of the lower jaw are generally well marked, except in simple fractures, through the symphysis. The special diagnostic signs are crepitus, more or less deformity of the contour of the lower part of the face, and unatural or excessive mobility. Pain is always present, and is increased by movements of the jaw. In the majority of cases the mucous membrane is lacer-

ated, giving rise to more or less hæmorrhage. There is excessive secretion of saliva, and on account of mixing with the discharges of the wound it decomposes, and causes an offensive breath. The normal occlusion of the teeth is changed, and this is well marked at the point of injury.

Case.—A man, twenty-nine years of age, came to me with a broken jaw in the morning on Thursday, March 14, 1907. Among other things, in his misery, he said that he had been hit on the jaw with a blackjack, knocked senseless, and robbed of \$3.60. The illustration shows that the patient is drawing his lower lip down so as to expose that part of the jaw where two teeth have been pushed out by part of the law where two teem have been pushed out of the blow received from the blackjack. I gave this patient the usual course of treatment, and it was some time before the could feel any semblance of relief. The difficulty encountered in treating this case was due to the fact that he came to me several days after he had been injured, and this he told me only two weeks after I started the treatment. However, after treating the case several months with fairly good progress, the patient suddenly failed to make his appearance for further treatment; and I am now of the opinion that either he is dead (from some other cause), or else is enjoying the best of health.

Considerable inflammation usually follows fracture of the jaw. This is accompanied by swelling and infiltration of the face and neck and is very often followed by troublesome abscesses and ne-

crosis of splinters of bone.

In fractures of the lower jaw, complications are possible, and among these possible complications are hæmorrhage from wounding inferior dental artery, paralysis of lower lip and chin, salivary fistula, abscess, necrosis, septicæmia, pyæmia.

Diagnosis.—This is generally a simple matter, but sometimes I have found it very difficult in locating the exact seat of fracture, especially if it is a sim-

ple one where there is no displacement.

Now, where there is any doubt about the fracture, I allow the patient to sit on a low chair, I standing behind. With both hands I grasp the jaw, placing the thumbs on the ends of the teeth and the fingers under the chin, by alternately depressing and elevating first one side and then the other. If fracture is present, crepitation will be discovered at the

point of injury.

There is one case which I distinctly recall in the month of January, 1907, at St. Bartholomew's Hospital. It was the broken jaw of a colored man who had been assaulted by some of his friends (?). Upon requesting the patient to close the jaw, I noticed his inability to properly do so. The fracture had been through the coronoid process, and in making this diagnosis, that which assisted me greatly was the inability on the part of the patient to properly

Prognosis of fracture of the lower jaw, as a general rule, is very favorable. The mortality is exceedingly low. Where the end is fatal this would in all probability be due to other complications, as

septic poisoning.

From my own experience in my clinic at St. Bartholomew's, I have observed that it takes about seven weeks for simple fracture of the lower jaw to unite. It takes about four months and even five months for a good union, where the fracture is compound, multiple, and comminuted.

Of course, we all know that the callous found at the fractured ends of the bone frequently causes deformity in a marked degree. However, this is only temporary. This afterwards disappears by absorption, and the facial lines are restored to their normal condition.

Treatment.—There are two conditions which are absolutely necessary to the successful treatment of fracture: First, the exact putting together of the fractured parts of the bone. Second, entire stability

of parts until union takes place.

A great many methods and devices have been introduced by which fracture of the lower jaw may be fixed. Great use is made of the interdental splint. Bandages are also employed in certain cases. I generally determine the particular method in each individual case by the location and extent of the fracture, and by the complications. Where fractures are complicated with laceration of soft tissues or hæmorrhage I treat them as wounds, viz., arresting hæmorrhage, rendering wound aseptic. After this, the fracture can be reduced. It is then that the appliance is selected and adjusted to maintain the stability of the parts.

Simple fracture with only slight displacement may be reduced and usually held in position by the simple four tailed bandage or the Barton bandage. In addition, may be used an external splint molded to the chin, or wires may be twisted around the firm teeth upon either side of the fracture, the wires to be passed through the approximal spaces at the

margin of the gums.

The angle fracture bands, screws, or wire are better still. These bands are of platinum or German silver. They are passed around the teeth and held in position by a set screw. This set screw passes through the tubes, which are soldered to the bands, which are drawn together by the screw until it tightly grips the tooth. This band is fastened to a firm tooth on either side of the fracture. The screw is then passed through the tubes. These tubes are prepared to receive the screw on the side of each band. By tightening the screw the fracture is approximated and maintained in position.

Another method is to make a band with a button on the side. Pass the wire around the buttons in the form of a figure of 8. This will approximate the fractured ends of the bone. In single fractures, in all locations of the jaw, this method is applied. In comminuted or multiple fractures, where the displacement is great and difficult to reduce, with this appliance there is constant danger of displacement, and the strain on the teeth to which these bands are fastened loosens them, the teeth becoming worthless

as points of anchorage.

The angle appliance cannot be used in those cases where the teeth have been loosened or dislodged, or where the jaw is without teeth. We are told that the best method in these cases would be to drill the maxillary bone and wire the fractured ends together. Up to this time I have not had the pleasure of drill-

ing fractured maxillary bones.

I wish to say just a word in regard to operations on the jaws. There are two things which should be remembered: I. Avoid any cutting operations on the external tissues of the face if the operation can be done through the mouth, so that no disfiguring scar may be left behind. I have seen time and again patients who were compelled to resort to operations on the face, either as a result of broken jaw or benign or malignant tumors, and whom it was a sight to look at after the patient had convalesced.

However, I think that, with the advance of science today, more care is being taken along these lines. Therefore the second point is, that where it becomes necessary to operate through incisions in the external tissues, care should be taken that the lines of incision follow the natural lines of the face. When operating on the lower maxillary, the line of incision should be kept under the lower border of the jaw for the same reason.

Another important factor in the treatment of fractures of the jaw is the hygienic condition of the mouth. And the most successful method will be that one which will permit of the most frequent cleansing without disturbing the appliance. There are a great many appliances which have been advocated and employed in various cases. My own method and motto is, "Use your own judgment."

It might be a bit of a strange fact, but you would be astonished to see the broken jaws which present at free institutions on St. Patrick's day, election day,

new year's day, and the Fourth of July.

Fractured jaws are interesting cases to treat, and I have found, through my hospital practice at least, that fractured jaws occur most frequently among the poorer and ignorant classes, and I regret to say that, owing to the fact that the fee is far and away less than the value of the services, nine tenths of the practitioners (medical and dental) "don't bother with it." But the satisfaction one feels in treating and relieving these poor wretches can only be appreciated by the one who is actively engaged in the

In closing, I want to say that a great number of fractured jaws are the result of quarrels among the very lowest of classes. It surprises me that the number of broken jaws are not on the increase on account of the heated newspaper discussions that we are constantly having on various topics of the

It has been said that were it not for the mouth, nine tenths of the gossip and the mischief of the world would be prevented. And very often, were it not for the mouth, there would be no broken jaws.

TREATMENT OF TUBERCULOSIS OF THE UPPER AIR PASSAGES.

Report on Tuberculosis and Lupus of the Nose, of the Nasopharyngeal Space, and of the Pharynx.*

By J. W. GLEITSMANN, M. D., New York,

Corresponding Member of the Vienna Laryugological Society, etc.

The invitation of your committee to make this report in conjunction with Professor Heryng was very pleasant to me as well as an honor, as I have made reports with the professor at former medical congresses and as we are in full accord on all major questions. We divided the work in this waythat he should report on the larynx, while I should report on the nose, the nasopharynx, and the pharvnx; I also took up, with the consent of your committee, the question of lupus. I have also complied with the wish of the committee not to refer to ætiology, the channels of infection, and the symp-

tomatology, and shall speak only on therapeutic questions.

Undoubtedly we have made progress in the treatment of tuberculosis of the upper air passages during the last decades, not only through the introduction of new methods, but also through stricter observation of indications in older modes of interference. But the surprisingly great variety of measures recommended, as indicated in the literature, proves that these have not been generally accepted and that they do not have the desired results when undertaken by others. My remarks made in a paper read before the New York Academy of Medicine in 1904 will even to-day find very little opposition, namely, that except among the absolute followers of a certain mode of proceeding, hardly two laryngologists will treat the same case of laryngeal tuberculosis in the same manner.

It is not my intention to review at length all the remedies which have been mentioned in publications. It will usually suffice simply to mention them and give the names of the authors concerned, especially as a great number of these methods of treatment are sufficiently known, and as others have been applied in only exceptional cases. The foot notes which I have added to the text will refer anyone who may be interested to the publications in question. But I shall go more into detail when speaking of newer methods or of such forms of treatment as, although they have been used for a longer period, have been improved upon and have stood the test

of time.

I. Tuberculosis of the Nose.

Gerber, in Heymann's Handbuch der Laryngologie und Rhinologie, distinguishes four kinds: Tuberculous ulcer, diffuse infiltration, tuberculoma, and lupus. Of lupus I shall speak later in a separate paragraph. The first thorough work on tuberculoma was written by Professor Chiari,2 based upon the twenty-one cases which had thus far been published. The treatment depends naturally upon the character as well as upon the intensity of the affection, and can therefore be studied from five points of view:

I. Local treatment by drugs. Of the older remedies, Seifert' reports good results in tuberculosis and lupus of the nose from paramonochlorphenol, a drug which also has seldom failed me in nonulcerating laryngeal infiltrations. Magenau' has used phenol sulphoricinate; other remedies are salicylated creosote plaster and poultices of a I in 1,000 sublimate solution. Of caustics, the following have been recommended: Undiluted carbolic acid, by Steward; lactic acid in different concentrations; a mixture of lactic acid, formalin, and chromic acid, by Barwell, who was successful in curing a tuberculous abscess of the sæptum only by painting it daily during a period of four months; and, finally, tampons of an eighty per cent, lactic acid solution, by Hinsberg. The latter should be kept in place for about three hours; when a longer period of application is desired, alternation with a weaker solution should be made.

Anul o

Grünberg' reports from Professor Körner's clinic in Rostock a cure of a microscopically verified, extensive tuberculous ulceration of the nose after an application of potassium iodide, which was ordered by a new assistant, who doubted the correctness of the diagnosis on account of failure with curetting, lactic acid, etc. Potassium iodide was afterward used in Professor Körner's clinic in many cases. Other good results have been reported by Wolters, and in a later communication by Grünberg," in a case of positive tuberculosis of the upper air passages. Holländer10 also prescribes in tuberculosis of the mucous membrane potassium iodide, but in combination with calomel, because he thinks that the former favors the chemotactic local action of calomel. The patient should take, a quarter of an hour before the application of the calomel, a tablespoonful of a five per cent. solution of potassium iodide, and then he either applies to the diseased site cotton saturated with calomel or injects into the tissue a one to two per cent. oily mixture of calomel, which should be well shaken before being used.

2. The hot air cauterization proposed by Holländer, which does not come in direct contact with the affected area, will be mentioned in the para-

graph on lupus.

3. Tuberculin preparations. It is a very pleasant duty for me to see these preparations so warmly recommended by Onodi and Rosenberg," especially as they have not been accepted so generally in America as they deserve, except with a few sanatoria and general practitioners. I am entirely of the same opinion as the two gentlemen are, but have been using the preparations also when other tuberculous inflammations were present. I never have seen disagreeable reactions or accidents from carefully increased doses. Only if there should be present extensive infiltrations of the larynx the greatest care or absolute forbearance becomes necessary to avoid the danger of suffocation from a swelling which may easily take place as a reaction. I have never seen a case of a patient becoming accustomed to the preparation.

Von Ruck12 has published the greatest number of cases of tuberculosis of the nose, cured with tuberculin preparations, which is known to me. He cites in the yearly report of 1903-1904 of his sanatorium in Asheville, N. C., eight such cases; in six patients tuberculosis was present in the sæptum, with perforation in two, and in two at the forward part of the lower turbinate. The preparation which is made in his laboratory, and which I also use, is a watery extract of tubercle bacilli, which has the advantage of being put up in three grades of concentration, of 1, 10, and 100, so that, for example, the tenth part of what is contained in a one gramme svringe of the second solution is equal to an entire syringeful of the first solution; thus further dilu-

tions do not become necessary.

4. Ray therapeutics. The Finsen light and the Röntgen rays have not been used so much in tuberculosis as in lupus. The difficulties of throwing the Röntgen rays into the deeper regions of the pharynx, larynx, and nasopharyngeal space have been overcome by the polyphos tube of Mader,10 who has had good results in other affections of the pharynx. During recent years good results have been reported from a protracted influence of the sun rays, which have been intensified by Tappeiner and Jesionek" by a permanent painting of the diseased location with a five per cent. solution of eosin during the raying. Brühl¹³ prefers a one per cent. solution of erythrosin, which solution produces a deep reaching effect of the yellow rays according to his statement; he then uses the rays from the yellow sodium light for two to ten minutes. Dr. Beck,16 of Chicago, has used radium, and, although his results in his first case were not satisfactory, has continued his experiments. Upon my inquiry, he has reported to me in a letter of April. 1907, three such cases, which I shall briefly cite:

Case I.—A woman, thirty-seven years of age, suffering from tuberculosis of the sæptum and secondary tuberculosis of the nose, was treated with Röntgen rays and later with radium. She was entirely cured, and according to the latest information was perfectly well eighteen months

Case II.—A woman, thirty-six years of age, suffering from extensive tuberculosis of the nose. She had used during five years all possible remedies without any results. During seven weeks she received applications of radium alternating with Röntgen rays. During the winter she went to Florida to recuperate, and returned entirely cured. No recurrence six months later.

CASE III.—'A boy, fourteen years of age, had been treated during two years with "Christian Science"; a sequestrum had formed in the back part of the nose, and he suffered from enlarged cervical glands. The sequestrum was removed, and for six weeks he was treated with radium of 1,000,000 activity. He still was entirely well sixteen months

The diagnosis of tuberculosis was confirmed in all three cases histologically and by other physicians.

5. Surgery. Although the remedies of which I have spoken have in some cases produced brilliant results, there are many disappointments to be reported. It is therefore only natural that we always come back to surgical interference.

Isolated tumors can be excised with a cold or hot loop, but this treatment is to be followed by a thorough cauterization of the affected area with lactic acid or the galvanic cautery. Ulcerations should be energetically curetted; diffuse infiltrations thoroughly spooned out, so as to remove all pathological material; for this purpose are used Volkmann's spoon and the several single and double curettes. If the infiltrations are too deep or too extensive to be removed by an intranasal operation, the nose should be split open or, if necessary, the parts should be resected, as resection of the sæptum has been performed by Onodi.1

Relapses are not rare, and these recurrences should be attacked with the same energy and perseverance as the primary affections. Steward18 has thus succeeded in finally curing a patient whom he had treated for three years.

II. Tuberculosis of the Nasal Accessory Cavities.

Two years ago I collected for a paper read before the American Laryngological Association twenty-five cases which I could find in the literature on tuberculosis of the nasal accessory cavities,10 to which was added, during the discussion, by Professor Killian a case of his own which had not been published. In such cases surgical interference is the only remedy, and it must be much more radical than in the nose, as all the bones which have been involved must also be removed.

The results of these operations are not encouraging, as only one cure could be reported in five cases of tuberculosis of the maxillary sinuses. But there are no reports about the later condition of these patients, with the exception of a patient of Dr. Coakley, of New York, who was operated upon in 1900, and who presented himself in 1907 without any

signs of tuberculosis.

III. Tuberculosis of the Postnasal Space.

Glas²⁰ reports a case, the only one of its kind, of a cure of tuberculous ulcers, the character of which had been proved histologically, with the expulsion of a sequestrum of the vomer, with potassium iodide, although he admits, on account of the surprisingly good results, the possibility of a complication with syphilis. Interesting also are the cases of Pluder21 and Schatz.22 The first treated a case of extensive tuberculosis of the nasopharyngeal space and pharnyx with curetting and lactic acid; a cure was produced, but with the formation of a synechia between the fauces and the palate. Schatz's patient suffered from growths in the posterior nares, tuberculomata of the nasopharynx, and lymphomata of the throat. An improvement appeared after the extirpation of the lymphomata, and a cure after the expulsion of the back part of the vomer.

Tumors, tuberculomata, are seen more frequently than abscesses, and Hajek²⁰ published the first case of this kind. The treatment can only be surgical, and the growth can be removed, according to its location and size and the preference of the operator, with the curette, the cold or warm loop, or the

nasopharyngeal forceps.

It would be very interesting to speak here of infection through the tonsils, a question which lately has become very prominent, viz., as to the physiological action of the tonsils, their action as organs of defense or as a theory of infection. But the limitation of this paper prohibits such a discussion. Latent tuberculosis of the hypertrophied pharyngeal tonsils is now generally admitted. But the reports on the frequency of the occurrence are not yet uniform. Lewin24 found in 905 cases, reported by nine authors, five per cent., Cornet's25 statistics include 1,745 cases in which tuberculous areas were demonstrated histologically in externally unsuspicious adenoid vegetations. Tuberculosis was found seventy-one times, or in 4.1 per cent. The number of cases of twenty-one authors range between negative results

reported by twenty per cent. of positive results. The latter figure, though, in only ten cases of operation

The extirpation of hypertrophied faucial tonsils is as important as is the necessity of finding out the possible existence of tuberculosis of the tonsils. Careful after treatment, such as by cleansing, cauterization of the wound, etc., is to be recommended, to prevent a possible infection and spreading of the tuberculosis after extirpation of the tonsils. In this connection I wish to say that I prefer an anæsthetic in the radical extirpation of even tonsils that are not infected. I have seen the development of tuberculosis of the lungs in consequence of neglect of such careful after treatment after an operation in an entirely latent affection of the tonsils; luckily the patient recovered under climatic and specific treatment.

We have to be, furthermore, on the lookout for the existence of infiltrated lymphatic glands. The removal of these glands should be insisted upon. Blumenfeld26 has lately demonstrated the importance of enlarged intrathoracic lymphatic glands, which appear sometimes in the course of adenoid growths, and which may be suspected to exist when bronchitis and catarrhal affections do not disappear after removal of the adenoids. In such cases general treatment becomes necessary. I myself have been able to prove the correctness of Blumenfeld's observations during the past winter in successfully treating a child that after such an operation still

suffered from a cough.

IV Tuberculosis of the Pharnyx.

Remedies which have given good results to physicians who used them, but which I do not find mentioned otherwise, are: Menthorol, advocated by Logucki,27 an addition of menthol to parachlorphenol as a corrigent; and anæsthesin, which Finder23 has found very useful by insufflation of the base of a tuberculous tongue. Recommended also are pyoctanin, papayotin, hydrogen peroxide, chromic acid, and carbolic acid; but the principal remedies are lactic acid, independently or after curetting, and trichloracetic acid, which latter has been repeatedly recommended, Veis²² being especially an advocate of it. The judicious advice of Schroeder and Blumenfeld³⁰ should be followed in localized cauterizations, especially when they are to be repeated. These authors remark that there exist cases of tuberculosis of the pharnyx which react unfavorably upon cauterization, and which only show signs of healing or are cured under a mild and simply disinfecting treatment.

The use of tuberculin preparations in tuberculosis of the pharnyx is well warranted, but the local treatment should not be neglected on this account. The injections show the best effect with observation of the opsonic index, that is, interruption during a descending index and resumption on an ascending one. Wood uses in addition the precaution of performing operations only during the later stage.

Some advocate the use of the solar rays, which treatment should extend over a long period. But Weiss reports the case of a tuberculous abscess on the lower lip which he had treated for months by painting with eosin without success, and which healed only when he included in the treatment the rays. The application took in all eighty hours; the evening before treatment an application of a fifty per cent. lactic acid solution was made by means of cotton compresses. Botey³³ cured an ulcer of the tongue by the application of radium during a period of several weeks, each application lasting thirty to forty minutes. Surgical interference, but only in healthy tissue, will become necessary in tuberculosis of the tongue which cannot be improved by curetting or the use of lactic or trichloracetic acid. The results will then be similar to those of operations for carcinoma in the first stage, as was reported by Butlin in the British Medical Journal for May,

Tuberculosis may also attack the lingual tonsil, the uvula, and the hard and soft palate, and we find in the literature the reports of perforations of the latter. These complications are very dangerous and make energetic interference necessary. Katz™ has cured such a perforation in a tuberculous patient by removal of the edges with the galvanic cautery loop and lactic acid. Tuberculous synechiæ appear very seldom, and only Loewey reports, from the clinic of Schroetter, a case of complete adhesion of the soft palate with the wall of the fauces; this adhesion was separated during the treatment and remained so. The case history of this married woman, which takes in a period of over thirteen vears, is also interesting for other reasons, and it demonstrates that even severe cases can be cured if the physician is patient and devoted and the patient is persevering. The patient suffered during her illness from tuberculosis of the lungs, larynx, and pharvnx. Tracheotomy was performed, later the synechia of the pharynx was separated, and finally the larynx was dilated with tin bolts to make the removal of the cannula possible. The lungs were finally thoroughly healed, as bacilli were not found a year and a half later, and a hoarse but audible voice took the place of the former aphonia.

It is absolutely necessary to remove thoroughly the hypertrophied palatal tonsils, whether they show any signs of tuberculosis or are without any visible affections in tuberculous patients. Special attention should be paid to both the poles; the lower and especially the upper continuation should not be overlooked. Amygdalotomes are not well adapted to these cases, and I prefer for the entire excision of the tonsils the spoon forceps of Hartmann or of Grünwald. The after treatment is very important. and we cannot do without silver nitrate, lactic acid, etc. Professor Chiari, some years ago, called attention to the infiltrated glands and urgently advised the excision of such localized lymphatic

I do not think it is necessary to give a detailed description of the surgical intervention in tubercu-

"Market for collection of the Market for the Market "Berliner klinis, o W o'enselvift, 1800, Nos. 4" and 4" losis of the pharynx, especially as most of these operations have been described under the diseases of the several organs, and as we are all well versed in the use of and indications for scalpels, curettes, excising instruments, galvanic cauteries, etc. But I wish to call attention to a point on which I have spoken before, that is, not to stand idly by in cases which seem to be hopeless, but on the contrary to double our efforts even if they should only be crowned with success in exceptional cases. An example of this kind is the case which I reported in 1890, at the International Congress in Berlin, and which since then has been mentioned in the literature. It was the severest case of tuberculosis of the pharynx and larynx which I have seen in a practice of forty years, and one which I always took for a primary attack. The patient, whom I have lately seen, is in the best of health, weighs more than before her illness, has given birth to two healthy children, and never has had before and after any signs of lung tuberculosis.

Gluck⁸⁷ has shown by the description of his method of operation and demonstration of patients at the Convention of German Naturalists in 1906, and in the Berlin Laryngological Society, November, 1906, that even the most desperate cases of tuberculosis of the upper air passages are accessible to surgery. Of thirteen patients whose cases had been far advanced and upon whom radical operations had been performed, eleven were cured; among them a man upon whom he had resected, on account of extensive hyperplastic tuberculosis, the tongue, the thyreoid, the larynx, the upper part of the trachæ and of the œsophagus, the pharynx, and the large vessels of the right side.

Lupus.

I can make a very short report on lupus, as the pathological process of this disease is always the same, although the objective manifestations very often present a different picture. This fact has only lately been emphatically demonstrated by Cadoche. We therefore find useful the same remedies which I have mentioned in the treatment of tuberculosis. As I do not wish to repeat myself, I shall only give such remedies as are either especially recommended for lupus or which I have not mentioned before.

Among the chemical remedies, pyrogallic acid has been very well endorsed, among other authors, by Onodi and Rosenberg," who state that it has a certain elective efficacy. There have also been used painting with a fifty per cent. solution of zinc chloride, by Heddmann; painting with ten per cent. formalin, also in combination with lactic acid, by Tretrop; " rubbing with twenty per cent. paramonochlorphenol, by Seifert: 2 and ethylchloride, but the reports about this remedy are less favorable.

Holländer's hot air cauterization without direct contact consists in an application of air heated to from 300° to 400° C. (572° to 752° F.) to the

of Manager, but the activate both over Manager and All the destruction of the manager and the second activate and the second activate and the second activate activate and the second activate a The set and never the set of the

affected area without touching it. Favorable reports have been made about this treatment, by which ischæmia of the skin is produced; the lupus cannot take part in this anæmia on account of deficiency of contractile tissue, and while the skin shrinks the lupus becomes more exposed; it is then heated to such a degree that the bacilli are killed and necrosis appears. Holländer has also split open the nose to expose the deeper tissues to the heat. Adrenalin increases this action. Among a hundred cases he hardly found one where the patient did not react to the treatment; among the cases were three laryngotomies.

I shall not refer to such surgical interferences as ignipuncture, thermocauterization, galvanic cauterization, curetting, and excision, as they offer nothing new and as it can be taken for granted that they are

known to all.

Ray therapeutics has a wide field in lupus, and the Finsen light especially gives good results in lupus of the nose. Schiff" asserts that he was the first to use Röntgen rays, which are at present employed quite frequently. Interesting is the observation of Hull, who explains the results of the action of the Röntgen rays upon lupus by the development of opsonins, through which action the microorganisms become an easier prey to the phagocytes. He comes to this conclusion from the successful raying of a lupus after a careful treatment with tuberculin, which stimulated the formation of opsonins, while before its use the lupus did not react to the

Some others have also used radium, and Botey 40 cured a case of ulceration of the point of the nose and lower turbinated bone in twelve séances of about thirty minutes each. In the discussion which followed the paper read by Meyer's before the Dutch Society Delseaux stated that he had found that adrenalin increased the action of radium. Sun rays with and without fluorescent substances, such as eosin, etc., have been applied to lupus. It must be stated finally that Nepovoshny's produced a serum in dogs by the artificial formation of a leucocytosis with the subsequent injection of the endotoxine of tubercle bacilli. Peterson" reports a good result in a case of lupus with this serum.

It is selfevident that the well known diatetic, hygienic, and climatic rules should be absolutely observed, as the greater number of patients also suffer

from tuberculosis of the lungs.

Surgical interference as well as lactic acid, and the galvanic cautery will always preserve their full value, and especially is the latter well recommended at present by many authors. Of the newer remedies, there have to be mentioned Holländer's hot air cauterization and the different kinds of ray therapeutics, the Finsen light, and solar rays with or without fluorescent remedies. We also may expect more and better results from continued experiments with Röntgen rays and radium. I myself have had the best results from surgical operations, the galvanic cautery, parachlorphenol in intact infiltrations, lactic acid in ulcerations, and tuberculin preparations in proper cases.

616 MADISON AVENUE.

A CASE OF POSTDIPHTHERITIC MULTIPLE NEURITIS WITH VESICLE INVOLVEMENT.

BY CARL D. CAMP, M. D., Ann Arbor, Mich.,

Clinical Professor of Nerrous Diseases at the Charlest of gan; Formerly Instructor iin Neuropathology and in Electrotherapeutics in the University of Pennsylvania, etc.

The noninvolvement of the sphincter of the bladder in multiple neuritis is usually regarded as so certain that it is used as a point in the distinctive diagnosis between multiple neuritis and spinal cord disease. Oppenheim in his textbook says that in exceptional cases of multiple neuritis there may be incontinence, but many other authorities hold that sphincter control is never lost. It seems that loss of control of the sphincters of the bladder in multiple neuritis is sufficiently rare to justify putting on record a case of postdiphtheritic multiple neuritis in which the patient had incontinence of urine. I have to thank Dr. William G. Spiller for the privilege of reporting this case.

CASE.—The patient, a Russian weaver, aged twenty years, was admitted to the nervous service of the Polyclinic Hospital on the 9th of April, 1907. During January of that year he was in the Episcopal Hospital of Philadelphia, suffering from typhoid fever. Soon after convalescence from the typhoid he was attacked with diphtheria and was removed to the Municipal Hospital. At the time he left the Municipal Hospital he noticed that his hearing was impaired, that his voice was weak, and that when drinking fluid there was a regurgitation of the fluid through the nose. About a week later he noticed that his hands and legs felt numb and weak, and at the same time he had in-continence of urine; "he could not hold his water," soiling his clothes and his bed. Examination at the time he was admitted to the Polyclinic Hospital showed a fairly well nourished young man, very deaf, and with a very weak voice. His gait was uncertain, ataxic, and there was voice. His gait was uncertain, ataxic, and there was bilateral foot drop, more marked on the left side. His station was poor, and the sway was made worse by closing the eyes. There was no paralysis of the face, tongue, or extraocular muscles. There was a hyperæthesia in the ulnar distribution of the left hand and the grip of both hands was used. Power of flexion and extension of the legs was weak. Power of flexion and extension of the legs was fair, and he felt a pin prick normally, though he complained that his legs felt numb. The knee jerks and the Achilles jerks were absent, and there was no Babinski reflex. Ocular movements were normal. The pupillary reaction to light was prompt and was present though slight to accommodation. There was some tenderness on pressure in the muscles of the arm and over the perineal nerves, also on pressing the calf muscles. At an ear examination made by Dr. Walter Roberts the hearing of tuning forks showed Dr. Walter Roberts the hearing of tuning forks showed Rainnes's test to be negative on the left side and practically absent on the right side. It showed also a lateralization of sound to the left ear. Hearing of low forks (fifty vibrations) was lost in both ears. High forks (two thousand vibrations) were heard well in the left ear, but faintly perceived in right. Examination of the right auditory canal showed an almost destruction of the drum membrane with a granulating reproactory and a slight discharge. The with a granulating promatory and a slight discharge. The left ear showed some tenderness around the auricle, especially in front, and a considerable tenderness and swelling of the cutaneous meatus. There was no view of the ear drum on account of the swelling. The examination would point to extensive nerve involvement on the right side, with

probably obstructive deafness on the left side. Examination on April 22d showed that under treatment the hearing in the left ear had improved, but in the right ear it had remained about the same. He could dorsally

the a first the common in Provide Amerit, and the american and Controlled to far in the volume and the first controlled to Patrician and the American and the Patrician and th

flex the right foot slightly and had nearly normal movement of the toes. He could move the toes slightly on the left side, but not the ankle. His gait was slightly improved, but he was still very ataxic and had a marked Romberg's sign. He still had marked tenderness in the calves of the legs. There was a paralysis of accommodation, ordinary print becoming blurred at a nearer point than twelve inches. His voice was still weak, but liquids no longer regurgitated through the nose. ment of the toes. He could move the toes slightly on the

It is interesting in this particular case to speculate on the part played by the previous attack of typhoid fever on the production of the symptoms of deafness and vesical involvement, both of which are so very rare after diphtheria. It is well known that the toxine of typhoid frequently exerts its effects on the nervous system by producing deafness, and less frequently symptoms of myelitis. It may be, therefore, that in this case the typhoid toxine produced a condition of lowered resistance in these parts, making them the more readily affected by the diphtheria toxine.

300 SOUTH STATE STREET.

Our Readers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXV. How do you treat cholera infantum? (Closed

June 15, 1908.)
LXXVI. How do you treat acute articular rheumatism?

(Answers due not later than July 15, 1908.)

LXXVII. How do you treat varicose ulcer? (Answers

LANTH. How do you treat various ulter? (Answers due not later than August 15, 1908.)
Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$82. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not REQUINED) that the answers be short; if practicable, no one answer to contain more than six hundred wards.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and

answer must be accompanied by the writer's jut name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL. The prize of \$25 for the best essay submitted in answer to question LXXIV has been awarded to Dr. Henry C. Becker, of New York, whose article appeared on page 1244 of Volume LXXXVII.

PRIZE QUESTION LXXIV.

THE TREATMENT OF SUNSTROKE. (Continued from Volume LXXXVII, p. 1247.)

Dr. G. W. Longenecker, of Elsinor, Kansas, states:

Sunstroke, or more correctly speaking, heat stroke, or thermic fever, is an affection produced by exposure of the body to an excessively high temperature. This condition is usually seen in men working in the sun on very hot days. Persons suffering from sunstroke may die almost instantaneously, the result of failure of respiration and cardiac action. The majority do not live longer than two or three hours. Thus it will be seen that the prognosis is very unfavorable. Heat exhaustion must not be mistaken for sunstroke, as the treatment of these two conditions is exactly opposite.

In true sunstroke the symptoms develop suddenly. The surface is flushed and hot, the pulse quick, and either bounding or weak, the breathing rapid and shallow. The temperature is very high, ranging from 106° to 110° F.

The first step in the treatment is to reduce the excessive temperature. Rubbing with ice or the cold bath will accomplish the most good. The patient should be put upon a bed covered with a rubber blanket and rubbed with pieces of ice. An ice cap should be placed to the head and ice bags to the back of the neck and along the spine. If ice is not obtainable the cold bath or cold sponging may be used. The patient should be rubbed vigorously while in the bath and cloths saturated in cold water may be used to the head and neck instead of the ice bags. These should be changed every five minutes. If able, the patient should drink cold water. The cold enema is also one of the most valuable means of reducing temperature. A rectal tube should be attached to a fountain syringe and four or five pints of cool water thrown into the colon. This should be retained ten minutes if possible. Without removing the rectal tube the water may be allowed to escape and the injection repeated. To prevent premature expulsion, it is best to begin with the water near the body temperature and rapidly lower it by adding cold water in sufficient quantity to produce the desired temperature. The enema, with the ice rubbing or cold bath, should be continued until the temperature is reduced to 101° or 101.5° F. If ice or cold water is not at hand, water of a sufficiently low temperature may be obtained by adding ammonium nitrate, eight ounces to the quart. If the pulse is rapid and weak, stimulants should be used-strychnine, whiskey, and digitalis. If convulsions occur, chloroform should he administered.

After the temperature is reduced the patient should be covered lightly and closely watched, as the fever may return in a short time. Should this occur, the same treatment must be carried out until the temperature is again reduced.

When the temperature is under control the patient must remain quiet and should be kept under observation, as meningitis is likely to develop in two or three days.

The bowels and kidneys should be kept active, and a light nourishing diet prescribed. Tonics should be given and sedatives if necessary.

Meningitis is characterized by violent darting pains in the head. There may be little or no fever. The treatment of this complication requires heroic measures. Venesection is the best method for obtaining relief. The bleeding should be copious and may be done by opening any of the large veins of the arm. Veratrum viride and aconite may be given. Quinine is contraindicated. If life is preserved without vascular depletion, secondary changes in the brain may occur, causing insanity, imbecility, or optic atrophy. In addition to venesection the treatment of the condition is principally Tonics and sedatives should be symptomatic. given. Rest and light nourishing diet. When necessary rectal feeding should be used. Cold applications to the head and back of the neck may be useful. Strychnine and digitalis may be required in some cases.

The physician must be on the lookout for any

complications which may arise and if his patient recovers he may feel that he has won a great victory.

Dr. Robert A. Bachmann, United States Navy, observes:

Sunstroke may be conveniently divided into heat exhaustion and thermic fever or siriasis, two widely different conditions requiring almost opposite treatment.

Heat exhaustion is caused by a weakened physiological resistance succumbing to a high temperature not necessarily solar. It consists of a sudden syncope. For treatment the patient is immediately removed from source of heat, clothing loosened, if temperature is subnormal, placed in warm bath or surrounded by hot water bottles or blankets. Respiration and pulse are stimulated by strychnine, gr. 1/20; and atropine, gr. 1/100. Hot coffee is useful. For immediate restoration a whiff of ammonia is of service. Take rectal temperament repeatedly until it reaches normal. Let patient recover then in cool, dark room. Convalescence should require several days' rest in bed with tonics

and light diets.

Siriasis has been ascribed to infection (Samborn), actinic solar rays (Duncan), congestion of blood due to loss of fluid by sweating (Senftleben), hygienic errors, malaria, and acute diseases. It consists of a brief prodromal stage followed by coma; complete unconsciousness; hyperpyrexia; depressed respiration and pulse; contracted pupils; and dry, hot skin. These symptoms demand immediate and vigorous treatment. The hyperpyrexia is best combated by iced tub baths, and in severe cases where the fever reaches 108° to 110° F. by placing patient stripped on stretcher which has been covered by a rubber sheet, with head slightly raised to assist drainage, surrounding him with ice, rubbing ice on body and head, while ice water in fine streams is dripped over him from an elevation of five to six feet. Take rectal temperature constantly, and when it falls from 106° or 107° to 102°, or from 108° or 110° to 103° stop these measures. If temperature persists pack rectum with ice. Often the ice pack, ice water bath, ice rub, or ice water drip alone are sufficient to reduce the temperature, and instead of packing the rectum with ice, ice water enema can be tried. The guide in all cases is the thermometer, and the treatment must be graded according to the way the temperature falls. The skin should be rubbed vigorously all the time in order to bring the hot blood to the skin, thus preventing internal congestion and aiding radiation. Cool the head especially well with ice pack or a fine stream of ice water, played on forehead for a minute or two to prevent subsequent meningitis.

If malaria is suspected inject ten grains of quinine hydrochloride at once. Support the heart by a hypodermatic injection of tincture digitalis, thirty

minims, before bath.

After the temperature has been reduced, dry the patient well, wrap him in dry warm blanket to produce sweating, and place him in a cool, dark room.

In plethoric cases, with cyanosis, labored breathing, and high arterial tension, puncture one of the

median veins of forearm after constriction and allow 100 to 150 cc. of blood to escape. Some recommend transfusion of normal saline solution through the same needle. If convulsions occur give cautious inhalations of chloroform. Avoid atropine and strychnine. The former because the establishing of perspiration is desirable, and the latter on account of the irritation to meninges and spinal cord. The coal tar antipyretics are worse than useless. Where the respiration has apparently failed artificial respiration should be tried in every case. Seemingly hopeless cases have been saved that way (Chandler).

The after treatment consists of giving bromides in the event of nervous irritability coming on; tonics for the improvement of general nutrition and the prevention of later exposures that might cause a

relapse.

To prevent siriasis, alcoholic and dietary excesses, especially in meats, should be strictly eschewed by all people who are unavoidably exposed to heat and sun. The clothing should be light in weight, loose, and the under garments made of thin woolen fabric. Outer garments should be lined with thin orange red material. It is usually practicable to attach strips of this cloth so that the shoulders and spinal cord at least are protected. In going out in the sun a broad pith helmet lined with orange red lining and affording ventilation to the scalp should be worn. Further protection is obtained from an umbrella. Generous drinks of water and mild beverages, regular but not violent exercise, and avoidance of damp evening atmospheres are to be recommended.

Dr. Boyce, of Pittsburgh, Pa., remarks:

The first essential to success is instant and certain recognition of the condition. Textbooks give distinctive tables of heat stroke or insolation and heat exhaustion. In the presence of the typical case, even the tyro can dispense with the table. The crisp, hot skin, the flushed face, the throbbing carotids, the convulsed or at least stiffened muscles, the labored, stertorous breathing, and the type of stupor or coma give a picture as diametrically opposite to that of simple exhaustion from heat, as can well be imagined. The atypical case is to be distinguished rather from uraemia and from apoplexy. For this a temperature above 103° F. will usually suffice. It is to be admitted that certain cases of pontile hæmorrhage give a syndrome clinically indistinguishable from insolation. This condition is very rare and almost hopeless. So it seems the part of practical wisdom to ignore the possibility if there is a history of exposure to radiant

The diagnosis having been made, efficient hydrotherapy will prove (where circumstances make it practicable) the most satisfactory measure. One attendant should be set to chipping ice and wrapping it into packets of convenient size, to be placed about the head, along the carotids, in the axilla, and on the groins. One or more others should strip the patient, lay him on a rubber sheet, and sprinkle him from head to foot with ice water, sousing it on out of towels or sponges, or from a garden sprinkling can, or from a syringe with

rose nozzle. Light, active friction to equalize surface temperature is very useful. The time element is very important, and there should be no delay. Better to apply the best measures at hand, than to wait to transport patient any distance. At worst the clothing can be loosened about neck and waist, and cool water dashed from pitchers against temples

As soon as the hydrotherapeutic measures are well arranged the physician must consider blood letting, remembering that his training has left him more prone, in this regard, to the sin of omission

than to that of commission.

Venesection may sometimes be the primary measure, because immediate hydrotherapy is impossible. It may rank as the first adjuvant because of an excessively full and bounding pulse, or (when tension is only moderately increased) because of the prominence of coma of an apoplectiform type, or of labored breathing and cyanosis. If after half an hour of hydrotherapy the temperature is not lower nor the symptoms abating, bleeding is justifiable save only when pulse tension is actually below the

Chloroform is recommended for convulsion. It seems uncalled for save when assistance is scant and the violence of the convulsions interfere with other

Stimulants are often used, seldom needed. Saline solution by vein or cellular tissue may be indicated after free venesection. Otherwise our choice lies between ammonia for general prostration with impending death, atropine, gr. 1/60, if the chest is full of moist rales to the drowning point, strychnine, gr. 1/30, for the respiratory centre, or with sparteine, gr. 1/4 to i, for the heart.

Success will oftener be reached by steady perseverance with the methods mentioned than by an excited scurry down a longer list in the hope that

if one thing does not benefit another may.

As this is all emergency work a word as to extemporized means may be permitted. A towel or handkerchief and a pocket knife, razor, or button hole scissors are all that are needed for venesection. The tip of an ordinary medicine dropper is a good intravenous canula. Any physician should be able to give hypodermoclysis with a Davidson syringe, a piece of rubber catheter, and the needle from his hypodermatic case. Hydrant water with a heaping teaspoonful of table salt to the pint, boiled for ten minutes, is saline solution sufficiently near normal.

The temperature having been reduced, and the immediate danger being past, after care becomes important. Whatever is our theory as to the primary pathological mechanism of sunstroke, hypertoxicity of the blood is a demonstrated factor. It is important therefore to limit intestinal absorption. If the attack followed a heavy meal, or if the stomach seems distended and painful, or if there have been ineffective efforts at vomiting, gastric lavage is indicated. Two ounces of magnesium sulphate in saturated solution should be left in the stomach. Otherwise, ten grains of calomel in butter should be placed under the tongue, to be followed in a few hours by salines or a colon lavage. The kidneys are to be closely watched. If suppression of urine or other signs of renal insufficiency appear, we may

employ wet cups to loin, and veratrum or nitroglycerin, if blood pressure is high; intravenous saline, caffeine, digitalis, and sparteine if it is low.

For the headache which so often follows, I employ chloral; bromide and ergot, if it is dull, general, and accompanied by drowsiness or injected conjunctivæ. When it is localized and lancinating acetphenetidin is more effective.

After recovery we must insist upon a considerable period of mental and physical rest. The use of bromide and ergot in this period, to be followed by small doses of iodide, seems rational, though it is difficult to demonstrate an effect clinically.

Finally the patient must be instructed in the prophylactic treatment as follows: During hot weather avoidance of exposure and of special mental and physical exertion, abstinence from alcohol and from diet excessive in quantity or indigestible or irritating in quality; rest and hydrotherapy on the slightest premonitory symptom of another

Dr. Henry Lynde Woodward, of Cincinnati, says:

In treating sunstroke the first and most important feature is the quick reduction of the excessive temperature; this is best accomplished by the external and internal application of cold.

The patient, stripped of clothing, is placed in a tub of ice water, an ice bag is placed on the head and the body rubbed all over with ice. At the same time a high rectal injection of ice water is given. Often the hypodermatic injection of nitroglycerin just before the bath will aid in the rapid loss of heat, by helping to dilate the peripheral vessels.

If the heart is flagging stimulants as strychnine or caffeine are indicated. Often this vigorous treatment will in fifteen minutes reduce a temperature of 108° or 109° F., or even higher, to nearly normal, and the patient, who has been comatose or delirious.

will regain consciousness.

The patient is then rubbed dry and placed in bed with light covering, and evaporation aided by fan-

ning, an electric fan being best if at hand.

The after treatment consists of an ice cap to the head, with the fan, or at least good ventilation, and stimulants, if required. A liquid or light diet with plenty of water will aid in the prevention of nephritis, which is a frequent complication. If hyperpyrexia recurs, which is not frequent, the ice bath can be repeated as often as necessary. If a tub is not at hand the patient can be wrapped in a sheet, packed about with ice, and rubbed with ice, or if ice cannot be obtained, sprinkling with cold water from a hose or watering pot is a fair sub-

While this initial treatment may seem severe it is life saving in many instances, and the sooner it can be applied the better.

Dr. T. Haven Ross, of Cato, N. Y., writes:

Sunstroke, or more accurately thermic fever, the coup de soleil of the French, may be considered in three grades: The overwhelming attack which is always fatal instantly or within a few minutes, the acute seizure which may kill in half an hour or more, or from which, under appropriate treatment, the patient may recover, or pass into the

Marie Jok 1

last class of subacute, or chronic cases. Excessive heat is the cause of all, and our treatment applies to the acute and subacute cases, as the fulminating ones are fatal before any treatment can be instituted, and the chronic cases so called are really sequelæ of the acute.

As the oral or rectal temperature may approximate 108° to 112° F. at the time of seizure the essential thing is to extract the excessive heat from the body as soon as possible; next support the heart and respiration until normal conditions are regained. Get the patient quickly into the shade, if in the open, in any case to as cool a spot as is available where fresh air is plentiful. Place him prone and remove all clothing and pour cold water over him by the bucketful until the temperature drops to 99° or 100° F. Then give him 1/2 ounce of whisky containing 10 drops of tincture of digitalis, and get him to bed. Watch the temperature and heart. If the temperature rises again, as it is apt to do, either wrap him in sheets wet with cold water, rub him from head to foot with pieces of ice, or place him in a bath tub full of water at 60° F. and cool it gradually with cold water or ice to the desired point. If needed repeat the whiskey and digitalis as indicated, The temperature then usually drops to normal, or nearly so, and stays there. After returning the patient to bed if the temperature should again rise repeat the cooling process. When I am quite satisfied that the temperature is under full control I often give, always if nervous unrest appears, a small dose of morphine and atropine hypodermatically. Follow up this active treatment with a general tonic, paying especial attention to the hepatic con-

tion. Thus will be avoided annoying sequelæ. In cities an ambulance will be called for the victim of heat stroke, and it should be provided with ice. The patient should be stripped naked as soon as he is in the wagon and rubbed all over with ice continuously the whole way to the hospital or his home. I have known of deaths from sunstroke caused by the delay in treatment due to the lack of ice in the ambulance. As a few moments may mean life or death the ambulance surgeon, if he has no ice at hand, should give the cold water treatment on the spot before starting for the house. Cold water and something to carry it in are almost always at hand. Arriving at the hospital, or the home, if it contains a bath tub, I prefer the immersion at 80° F. gradually cooled with ice, to the other methods. The patient is best wrapped in a dry sheet and lifted into the tub, and it may require an hour therein to reduce the temperature sufficiently. I do not approve of the use of the coal tar derivatives as advocated by some, because of their depressing effect on the heart.

As already remarked, some patients are so overwhelmed at once that there is little or no time to do anything, but if there is a chance at all bring cold to bear on the naked body; clothing interferes with evaporation. If I were so situated as to be unable to use cold I should not hesitate to bleed the patient at once as his only chance.

It may be well to caution against carrying the cooling process too far. In a few instances I have seen the temperature reduced to normal without any return of consciousness, and have then applied

counter irritation to the scalp (shaven if possible) and nape of the neck in form of rapid blisters, with good results in most cases, but two patients, according to my records, died in coma with a normal rectal temperature.

As to sequelæ, the one almost invariably met with is inability to endure heat, natural or artificial. Care must be taken to avoid heat, especially moist heat, as the moisture in the air retards or prevents radiation of heat from the body, there may be cephalalgia, vertigo, tremors, dyspepsia, toxic intestinal neurosis, and even epileptic seizures. The most serious is a condition of chronic cerebral and meningial irritation following thermic fever. The diet should be arranged so as to be highly nourishing without being irritating, the liver should be carefully and persistently looked after, and general tonic measures, external and internal; instituted and persevered in. Where any signs of meningitis appear I use freely, even brutally, the actual cautery and a long course of mercurials and iodides. Persistence will win, but it may take months.

Dr. George B. Foster, of Lynn, Mass., says:

Teach the people the preliminary symptoms, which taken as warning may prevent the more dangerous symptoms. They are, as a rule, nausea, cramps, increasing weakness, vertigo, headache, and cessation of the respiration. These symptoms should warn, the person of his danger, and should persuade him to seek a cooler place.

When a patient suffering from sunstroke comes under the care of a physician he should be treated as follows: I. Remove all clothing. 2. Place patient on bed, which should be covered with a rubber blanket or oilcloth. 3. Place large quantities of ice about the head. 4. Apply cold to body. Ice water applied with sponges or cakes of ice may be rubbed over the body, especially the abdomen, chest, and back, and while this is being done the patient should be rubbed thoroughly and briskly to bring the hot blood to the surface.

In the more severe cases cover the patient with a sheet, upon which place pieces of ice, and then ice water in dippers at a distance of five to ten feet are dashed with force upon the patient for thirty or forty minutes, according to the fall of temperature. In cases where this fails, pouring a fine stream of ice water on the forehead for only a few minutes may give results.

Digitalis should be given hypodermatically during the bath; thirty or forty minims should be used, except in cases where the face is cyanotic, pulse bounding, and the heart laboring; venesection should be practised in these cases, intravenous injection of normal salt solution should be freely used, and later digitalis in small doses.

When temperature reaches 102° F. (temperature should be taken by rectum) throughout this cold treatment, cold applications should be stopped and patient allowed to lie in bed covered only with a thin sheet.

Watch temperature; if it bounds up again cold must be applied again with same care.

In cases of prolonged unconsciousness nourishment and stimulants are given by means of the stom-

ach tube. Artificial respiration should be used in severe cases, persisted in for half hour or more.

After the fever has been reduced watch the patient carefully for complications. Meningitis sometimes develops; venesection is the best treatment, although vascular sedatives may be tried, as veratrum.

After treatment should consist in light diet, stimulants, fresh air, and sudorifics, liquor ammonii ace-

tatis in large doses.

Heat exhaustion.—Use heat instead of cold, body recumbent, head low, use hot water bottles or hot bricks, or give hot bath 105° to 110° F. As stimulants use brandy, one ounce; if patient can't swallow, give brandy by rectum or whiskey and digitalis hypodermatically. Watch temperature.

Dr. H. B. Blakey, of Columbus, Ohio, states:

Sunstroke must be distinguished immediately from coma and heat exhaustion. In heat exhaustion we find the patient in a state of collapse or extreme prostration, with a small pulse, the temperature possibly subnormal, with a history of exposure to great heat. In sunstroke we oftentimes find the patient unconscious, the face flushed, the pulse rapid and soft, the temperature varying from 107° to 110° F, with a history of direct exposure to the sun's rays. The temperature should be taken immediately, in every case, as much depends upon this finding.

A case of sunstroke demands an immediate lowering of the temperature. Hydrotherapy is the best means by which to accomplish this result, using: I. The tub bath. The patient should be stripped and placed in a tub of water at a temperature of about 70° F. The water should be further cooled, by adding ice, until the temperature of the water is about 50 degrees. 2. The ice pack. The patient should be stripped and placed in a wet sheet; ice should be packed along the trunk, the extremities, under the arms, and around the neck. At the same time, part by part, the whole body should be exposed and rubbed with masses of ice. 3. If neither the tub nor the ice pack is available, it may be expedient to place the patient under a faucet, turn the hose on him, place him under a pump, or pour bucket after bucket of water over him. The use of an ice water enema has yielded good results as an accessory to these methods.

As the temperature falls from one to two degrees after the patient has been removed from the bath or pack, it is important to remove the patient when the rectal temperature is not less than 100° F.

The use of antipyretics is permissible as an aid, but never as a substitute to hydrotherapy. Antipyrine, in 15 grain doses, or quinine sulphate in ten grain doses, has yielded good results in my hands.

The complications following immediately upon or during a case of sunstroke are: Intense asphyxia, convulsions, recurrence of the hyperpyrexia, and change of temperament. These demand treatment as follows: Intense asphyxia, with agonizing headache and continuously high fever, indicates bleeding. From twenty to thirty fluid ounces of blood should be withdrawn. There is no doubt that this measure is one of high importance and should be resorted to carly in these cases. Convulsions should be controlled by inhalations of chloroform; or the hypo-

dermatic injection of ½ grain morphine, in adults, repeated, if necessary. The recurrence of the hyperpyrexia demands a repetition of the bath or pack. In these cases the symptoms of shock should be carefully watched for. The change in temperament is a striking sequelæ of sunstroke. Often the quiet, cheerful person becomes unruly and most irritable. These patients need watching for several months for symptoms of mental aberration.

The prophylactic treatment is almost self evident. In the heated periods every one should avoid exposure; alcoholic, sexual, or other excesses; and exhaustion, bodily or mental. The enunctories should be kept active; the clothing should be light. The diet should consist of fruits and vegetables, with the avoidance of fats and meats. Cool, pure water can be drunk in moderation. Those persons who have suffered from sunstroke should be particularly careful in these periods.

(To be concluded.)

Correspondence.

LETTER FROM LONDON.

coroners' Inquests.—The Catford Case.—Open Air Schools.— Appointments in Scotland.

London, June 16, 1908.

Mr. Troutbeck, the coroner for Westminster, has excited a good deal of criticism both among medical men and with the general public by his peculiar methods of carrying out the law. For some time past it had been his custom, in all cases where a post mortem was necessary, to get an expert pathologist to perform it, the medical man in charge of the case not being called even to give evidence. 1903 the British Medical Association called the attention of the Lord Chancellor to this practice of Mr. Troutbeck's, and, although Lord Halsbury (the Lord Chancellor at that time) expressed disapproval of the coroner's methods, he was unable to remove him from office, as this could only be done for mis-conduct. Mr. Troutbeck has now found another serious deficiency in the law which he feels called upon to remedy. He considers that the number of deaths subsequent to operations is rapidly increasing, and there are no possible means of knowing what deaths have been brought about or accelerated by surgical operations. He considers such deaths unnatural, and consequently he thinks all such cases should be reported to the coroner, who would decide whether or not an inquest was necessary. He took the first step in this reform by ordering an inquest on a patient who had died at the Bolingbroke Hospital after an operation for removal of a cerebral tumor, performed by Sir Victor Horsley. At the inquest Sir Victor Horsley protested that he failed to see why any inquest was necessary. It was quite a new departure, and could serve no useful purpose. The same argument for holding an inquest could be applied to any case of a patient who died after receiving surgical or medical treatment, because it might always be contended that the giving of some drug or the adoption of some surgical procedure was an "unnatural" event. Mr. Troutbeck, in his address to the jury, stated that he believed the peo-

ple of this country were in complete ignorance as to the proportion of deaths accelerated by surgical operations. It was a serious matter and one for which a legal remedy was undoubtedly required. He certainly did not intend to let the matter rest. an interview published in yesterday's Daily Telegraph, the coroner further explained his position. He thinks the present mode of procedure is in pressing need of amendment. He suggests that the certificates in cases of death following operations should contain fuller details than the usual death certificates. He also thinks that coroners should be given the power to order a post mortem whenever they think it advisable, as the information thus obtained would enable them to decide whether an inquest was also necessary. The performance of post mortems should be undertaken only by skilled pathologists, as is the case in France and Germany, and not by general practitioners. The coroner's act of 1887 is certainly antiquated and needs amendment. In fact, there is a bill which is likely to be passed by the present Parliament which will do away with the viewing of the body by the coroner's jury, a useless practice, and there are several other points in the act which need amendment. But some of Mr. Troutbeck's suggestions are, to say the least, impracticable. If an inquest was to be held in every case of death after a surgical operation, the result would be that many an operation performed to give a patient his only chance would not be undertaken for fear of the publicity of an inquest, which would be damaging to the surgeon's reputation and painful to the patient's relatives and friends, and could do no possible good. The methods of Mr. Troutbeck are severely criticised in the British medical

Among the cases dealt with by the Penal Cases Committee of the General Medical Council is that of Dr. John Papa Nicolas, known as the "Catford Dr. Nicolas was a young medical man practising at Catford, in the southeast of London. Before beginning practice on his own behalf he had acted as assistant to a Dr. Atkinson in the same district, but no bond had been given, and there was no argreement between them as to restriction of practice in the neighborhood. The charge against Dr. Nicolas was that he had systematically canvassed for patients in Catford and had disparaged the professional skill and ability of his principal. The Council took up the consideration of the case last November, and it was adjourned to the present session. Notwithstanding a very skilful defense by Dr. Nicolas and his legal advisers, the verdict was given by the Council, after a protracted considera-tion of the case, that Dr. Nicolas was guilty of infamous conduct in a professional sense, and his name was directed to be erased from the Register. An appeal has been lodged against this decision, which will be considered in due course, and there is also a libel action pending with reference to the same case. The whole matter must therefore still be considered sub judice. During the consideration attacked by Dr. Nicolas's legal representative, and this matter will also come up for further consideration. There is no doubt that the judicial functions of the General Medical Council are beset by many difficulties. The skilful defense of this case has greatly embarrassed the Council, and their ordinary business has been hampered very considerably. Besides this, the expenses of such a protracted case will amount to no inconsiderable item, and if the case should be brought before the general law courts, which is very probable, the expenses will be considerably increased.

The Education Committee of the London County Council tried the experiment last summer of establishing an open air school. The report just issued gives a very glowing account of the success which has attended the experiment. The children selected for instruction were all weakly or anæmic, but after the period of schooling in the open air the health of every one of them decidedly improved. In the case of some children suffering from active disease this was entirely arrested. Encouraged by their success, the committee propose this summer to hold three open air schools. Each will accommodate seventy-five children, under a head teacher, three assistant teachers, a nurse, and a cook. The results of this experiment will be awaited with interest.

Two important medical appointments have been made in Scotland. In Glasgow University, the chair of the practice of medicine has been vacant since the death of Sir Thomas McCall Anderson. The vacancy has now been filled by the appointment of Dr. Samson Gemmell, who occupied the chair of clinical medicine. Dr. Gemmell is an M.D. of Glasgow University, and for some years acted as assistant to Sir William Gairdner. The second appointment is that of Mr. Francis Mitchell Caird, M.B., C.M., F.R.C.S.E., as regius professor of clinical surgery in the University of Edinburgh, in place of the late Professor Thomas Annandale. Mr. Caird was a dresser and clinical clerk under Lord Lister while he was still professor of clinical surgery in the University of Edinburgh. He is perhaps the most competent operator in Edinburgh in cases of abdominal surgery.

Therapeutical Notes.

Remedy for Coryza.-A combination that is said to control a cold in the head within from twenty-four to forty-eight hours if taken at the onset of the attack is represented in the following prescription, taken from Les nouveaux remèdes, for May 24, 1908:

Sodium Sulphite in Rhus Poisoning.-The application of a supersaturated solution of sodium sulphite in water is recommended for the treatment of rhus poisoning by Briggs (The Therapeutic Gazette, May 15, 1908), who says that complete recovery takes place within three or four days after

such an application, even in the most severe cases. The solution leaves the parts with the appearance of having been whitewashed. It quickly relieves the burning, itching, and swelling, and causes no irritation. The application is also effective in the eruption, which is apt to return each spring in persons who been once attacked.

For Cephalæa.—The Journal de médicine de Paris, for April 4, 1908, cites the following prescription of Semon for the relief of headache:

| P_{k} | Acctanilide,gr. xxxv; |
|---------|---------------------------------|
| | Monobromated camphor,gr. viiss; |
| | Sodium salicylate,gr. xv; |
| 3.6 | Extract of hyoscyamus,gr. iss. |

Sig.: One capsule every hour until five are taken, or until relief is experienced.

The Treatment of May Fever.—Menier (La Quinzaine thérapeutique) recommends the inhalation of mentholated chloroform, containing 4 per cent. of chloroform, where there is excessive secretion, this to be used in conjunction with a nasal spray of a 1 in 2,000 solution of adrenalin. For the eyes he suggests an application of one drop of a solution containing two per cent. of eserine sulphate or of a five per cent. solution of pilocarpine nitrate. The asthmatic forms of the disease are best treated with antispasmodics. In mild cases the use of belladonna or the valerianates is indicated, as in the following combination:

| \mathbf{R} | Extract of belladonna, | | |
|--------------|------------------------|------|--------|
| | Syrup of poppy, N. F., | | |
| | Cherry laurel water, | | |
| M. | Distilled water, | | 311SS. |

If valerianates are preferred the following may be prescribed:

| \mathbf{R} | | ammonium | | | |
|--------------|-------------|--------------------------|-----------|--------|-----------|
| 3.5 | | of valerian, | | | gr. xviii |
| | ft. pil. No | o. xxiv. 1 every thre | e or four | hours. | |

When the asthmatic attacks are not severe the use of bromides is resorted to in the following combination:

| P_{i} | Potassium bromide,5v; |
|---------|--|
| | Tincture of lobelia, |
| | Tincture of grindelia robusta, |
| | Camphorated tincture of opium, |
| | Syrup of bitter orange peel,3x; |
| | Decoction of senega, |
| Μ. | Sig.: One tablespoonful three times a day. |

Where the asthmatic attacks are particularly severe resort may be had to morphine or heroin. It is always advisable to look for some lesion in the nose as the source of the trouble.

For Seasickness.—In the Journal de médecine de Paris Schepelmann is credited with the following remedy for seasickness:

| B | Cocaine | hydrochloride,gr. iii | |
|----|-----------|-----------------------|---|
| | Tincture | of iodine,gtt. xxx | ; |
| M. | Distilled | water, | ٠ |

Sig.: One tablespoonful for a dose, to be repeated two or three times, as needed.

The Treatment of Bronchial Pneumonia.— Hirts, of the Necker Hospital, Paris (Revue medico-pharmaceutique, March 1, 1908), advises the use of the cold pack in the treatment of bronchial pneumonia, allowing it to remain in place from two to three hours, instead of the shorter period of twenty minutes usually allowed. This is followed by energetic massage and a renewal of the cold application. Where the heart is weak a warm or tepid bath is to be preferred to the cold pack. Renault, of Lyons, bathes the patient in water at a temperature of 100° to 102° F, three or four times during the day and night, sometimes every two hours. It is important to sustain the action of the heart. The duration of the attack is much shortened by this treatment. The mustard bath which is sometimes used exerts an energetic revulsive action. In critical cases the patient may be seated in a warm sitz bath and water cooled to 60° F, dashed on him.

Internally the following may be administered for

its stimulant and sudorific action:

| F_{i} | Brandy, | | | , |
|---------|----------|---------|------|--------|
| | | | | 10kxx; |
| | Syrup of | tolu, | | |
| | Syrup of | acacia, | | |
| M | | | | |

Oxymel of squill is a good expectorant, which may be given in doses of five to twelve drachms in the following draught:

| R | Syrup of | coffee, . | | | | | | | | | | | | Ĵν | 7 |
|-----|----------|------------|--|--|--|--|--|--|--|--|------|------|--|-----|-----|
| | Syrup of | digitalis, | | | | | | | | | | | | 3v | 7 : |
| | Oxymel o | of squill, | | | | | | | | | , | | | .31 | v. |
| 17. | | | | | | | | | | | | | | | |

The cough of the tuberculous patient may be relieved in various ways, either by suggestion or by means of drugs. During the day chloroform water may be used, but at night a hypnotic of the nature of chloral is given by preference. A pill of the following formula is given with good results:

| | of hyoscyamus | | |
|-------------|---------------|------|--------|
| | ed antimony, | | |
| | powder, | | |
| M. ft. pil. | ion of roses, | | .q. s. |

Sig.: One pill every three hours.

For the relief of the pains in the chest suffered by the tuberculous patient morphine is best, but when its use is contraindicated the application of the following liniment will be found beneficial:

| \mathbf{R} | Guaiacol, | | \\\XXX; |
|--------------|----------------------|---------------------|---------|
| | Tincture of iodine, | | |
| | Glycerin, | | |
| M. | et. Sig.: Apply as a | paint once or twice | daily. |

A Tonic for Tuberculous Patients.—The following tonic mixture is prescribed in cachets by Sergent (*Journal de médecine de Paris*):

| P_{i} | Calcium carbonate,gr. 1; |
|---------|------------------------------|
| | Tricalcium phosphate, |
| | Calcined magnesia,gr. xviii; |
| | Sodium chloride,gr. xviii. |
| 3.4 | ft at div in cachet No vii |

Sig.: One cachet three or four times daily with meals.

Tonic Arsenic Pills.—Lesné recommends the following in La Clinique for May 2, 1908:

| P_{μ} | Sodium | cacodyla | ite, | | | | | .gr. v; |
|-----------|----------|----------|------|------|---|------|------|-------------|
| | | of cinch | | | | | | |
| | | oxalate, | | | | | | |
| | | rhubarb | | | | | | |
| | Pulveriz | ed nux | von | iica | , | | | gr. 1. |
| M | ft nil N | To vii | | | | | | |

M. ft. pil. No. xii.

Sig.: One pill to be taken before the two principal meals.

NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal and The Medical News.

A Weekly Review of Medicine.

SUBSCRIPTION PRICE

Under Domestic Postage Rates, \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, JULY 4, 1908

ANATOMICAL NOMENCLATURE.

On the appearance of Dr. Lewellys F. Barker's Anatomical Terminology, with Special Reference to the [BNA], which gave the nomenclature adopted by the German Anatomical Society, commonly known as the Basle nomenclature, we took the liberty of objecting mildly to some of the terms included in it, though we gave to most of them our unqualified commendation (see the New York Medical Journal for April 13, 1907, page 702.) A German author, Professor Hermann Triepel, of the Anatomical Institute of the University of Breslau, in a recent communication to the society, objects to more than a hundred and fifty of the terms. For a copy of the pamphlet, entitled Denkschrift über die anatomische Nomenclatur der anatomischen Gesellschaft auf ihrer 22. Versammlung in Berlin vorgelegt am 22. April, 1908 (Wiesbaden: J. F. Bergmann), we are indebted to Dr. Achilles Rose, whose efforts in the interest of onomatological purity are well known.

Professor Triepel agrees with Dr. Rose that modern Greek scholars should be consulted when new terms are to be formed from Greek elements. As regards anatomical terms he particularly recommends the study of Papaïoannou's Δυατομική τοῦ ρθυαιώτου (Athens, 1896). He gives a list of terms by which he would replace some of those that have been accepted by the society. Many of them concern the proposed change of the terminations roidalis, roidealis, and roideus to roides, and a num-

ber of the other changes which he suggests are founded on a like regard for the preservation of classical usage. Some of them, however, rest on other grounds, and it is interesting to note them. He prefers von Bardeleben's antebrachium to antibrachium and the same author's (and some others') anulus and anularis to annulus and annularis. He would change arrector to arrigens and articulatio (meaning a joint) to articulus.

He remarks that atlas was originally the name of the seventh cervical vertebra, and in its present sense he would replace it by epistropheus. Calcaneus, he says, is only a noun, and not also an adjective, and so, as we understand him, calcaneum should give place to os calcanei. Chylifer should be replaced by chylophorus, diameter conjugata by Hyrtl's diameter recta, and coracoacromialis by acromiocoracoides. Cruciatus should give way to cruciformis or chiastus. For duodenum he would substitute Luschka's intestinum pancreaticum, and he prefers meninx fibrosa or meninx dura to dura mater, condylicus to ellipsoideus, lympha interna to endolympha, fascia hypogastria to fascia endopelvina, processus paracondylius to epicondylus, episcleridius or supraduralis to epiduralis, axon or vertebra cervicalis secunda to epistropheus (originally the first cervical vertebra), vesica fellis to vesica fellea, gastrocnemiæus to gastrocnemius, genioglossicus to genioglossus, glomeriformis to glomiformis, glomerulum to glomerulus, glutiæus to glutæus. hæmorrhoidicus to hæmorrhoidalis, hallex to hallux, hilum (by no means new) or porta to hilus, pars propria intestini tenuis to ileum, hypomoglenius or hypoglenius to infraglenoidalis, infraspinalis to infraspinatus, mesocarpius to intercarpeus, mesocondylius to intercondyloideus, incisura lunata interna to incisura intertragica interna, ischiacus to ischiadicus, intestinum vacuum to jejunum, lemphicus or lymphaceus to lymphaticus, ganglion lemphicum or nodus lemphicus to lymphoglandula, plicatura to plica, metacarpium to metacarpus, metatarsium to metatarsus, polygonus to multangulus, cervix to nucha, medulla prolongata to medulla oblongata, oculimotorius to oculomotorius, paracentrius to paracentralis, parotidicus to parotideus, crista ossis pubis to pecten ossis pubis (for the reason that pecten means the whole pubic bone), lympha externa to perilympha, periosteum orbitæ to periorbita, peroniæus to peronæus, nervus pyramidis to nervus petrosus, pinguicula to pinguecula, meninx vasculosa to pia mater, pleuricus to pleuralis, promuntorium to promontorium, psoites to psoas (really the genitive of \$\psi\oldsymbol{a}\alpha dus (which, he says, ought to make one ashamed of himself), tunica nervea or tunica neurica to retina, glandula sebipara to glandula sebacea (literally a gland consisting of tallow), lunatus to semilunaris, sutura squamata to sutura squamosa, sternicus to sternalis, hyparachnoides to subarachnoidealis, superficialis to sublimis, mandibularis to submaxillaris, sudorifer to sudoriferus, hyperchorioides to suprachorioideus, hypercondylius to supracondyloideus, hyperomoglenius or hyperglenius to supraglenoidalis, supraspinalis to supraspinatus, sympatheticus (in accordance with British and American writers) to sympathicus, serum articulare to synovia, serosus to synovialis, thoracicus to thoracalis, cartilago tracheæ to cartilago trachealis, ephippium to sella turcica, umbilicus to umbo membranæ tympani, pennatus to unipennatus, and urinalis to utrinarius.

Free as we are of any special objection to most of these proposed changes, we must pause to consider to what extent our already overburdened vocabulary would have to be enlarged if other branches were to furnish neologisms to match these anatomical specimens. What would the medical dictionary of the future become? Moreover, we do object to digitus as a substitute for digitatio (meaning digitation) and to mylohyoides, omoplatohyoides, and omohyoides, for we know of no classical Greek word which, transliterated into Latin, contains the letter h save at the beginning, unless it is preceded by r, or unless, in conjunction with, t, p, or c, it represents theta, phi, or chi. Our antipathy to hybrids is as great as Professor Triepel's, but we despair of eliminating all of them.

PSYCHIATRY IN BALTIMORE.

By the choice of Dr. Adolf Meyer to be director of the new Psychiatric Clinic and professor of psychiatry in the Johns Hopkins University, the directors of that institution have once more shown that breadth of mind and catholicity of spirit which have stamped Johns Hopkins almost from its very inception. The habit of seeking the best, no matter where it may be found, and the still greater ability of being able to get it, have set the standard in Baltimore, where imitation becomes the sincerest form of flattery.

We congratulate the university on its good fortune, and express the regrets which are widespread in the minds of those interested in psychiatry in New York State at the loss of so able and so valuable a worker as Dr. Meyer has shown himself in the Pathological Institute. Above all, the status of psychiatry will be the gainer, and one of the most important branches of medicine—that which looks to the care of the greatest of man's faculties, the mind—will, through the efforts of so well qualified an advocate, gain a place which the more spectacu-

lar sister branches have for so many years seemed to overshadow.

THE SPHERE OF THE TRAINED NURSE.

This was the title of an address delivered by an eminent Philadelphia physician, Dr. W. A. Newman Dorland, before the graduating class of the Philadelphia School for Nurses on May 27th. The address has now been published in pamphlet form, and we hope it will be extensively read by physicians, by those who govern nurses' training schools, and by other graduate nurses than those who heard it. Dr. Dorland vigorously defends the rights of the pupil in nursing, emphasizes some of the errors of nurses' curricula, and warns trained nurses of certain errors into which they seem prone to fall.

The education of a nurse, he says, does not properly require that she should be kept for months at such menial work as "scrubbing, washing, and the other ordinary kitchen duties," which, he remarks, bear no more relationship to her training as a nurse than a knowledge of horseshoeing or of cobbling would. Then, again, he has observed that favoritism is sometimes shown to individual pupils. "One favorite nurse," he remarks, "profits by an excess of bedside or out patient instruction, and another draws in the lottery of favoritism a special career as clinic nurse, while a third bears the brunt of official disfavor and rounds out her career as hospital drudge." Every matriculate, he adds, should enter the training school with the assurance that she is to have the benefit of the institution's facilities equally with all her associates, and he justly calls upon all the pupils, including the favored ones, to resent invidious discrimination.

Another piece of injustice to the pupils, although they are not apt to realize it, is the pretense of giving them an extensive medical education, "equal to at least a two years' course in a medical college." The intention should be, not to make poor doctors of them, but the best of nurses. "I believe," says Dr. Dorland, "that a superficial knowledge of physiology and anatomy, together with a thorough acquaintance with hygiene, will answer every purpose." But it is well, he thinks, that the nurse should have sufficient knowledge of pharmacy to enable her to make percentage solutions quickly and accurately. for such facility is "an excellent adjuvant to the ability to record a temperature, a pulse rate, and a pulserespiration ratio." The cramming of nurses with learning is, indeed, a mistake, but their training, as Dr. Dorland truly says, cannot be overdone.

The nurse should have some months of obstetrical training, and Dr. Dorland believes that an excellent innovation would be a course, covering some weeks

only, of nursing in the slums. Thus "her inventive powers would be taxed, and her experience in securing thorough asepsis under such difficult circumstances would be invaluable." Of course such nursing would be more than ordinarily disagreeable, but it would only be analogous to what the young doctor almost invariably has to go through with, and nobody knows better than he how helpful it is in his subsequent career. As for obstetrical nursing, it is amazing that so many women decline to enter upon it. Nothing could more endear them to their patients than good service during confinement and the puerperal period, and it is in satisfying their patrons that they must chiefly seek the steps to prosperity.

Dr. Dorland very properly warns graduate nurses against rapacity and the trade union spirit. Many a nurse, he says, causes the note "For twenty or twenty-five dollar cases only" to be inscribed opposite her name in a nurses' directory, and this, too, shortly after she has obtained her diploma and when she is virtually destitute of individual experience. "At one fell swoop," says Dr. Dorland, "she annihilates the years of experience that one would deem essential, and leaps at once into the seats of the mighty in her profession." She fancies that her diploma entitles her to make this move. Dr. Dorland thinks those physicians are right who say: "If she will not take the fifteen dollar case, she shall not have the twenty-five dollar case." And we think so, too.

CUTANEOUS PIGMENTATION AND THE MORPHINE HABIT.

At a recent meeting of the Medical Society of the Paris Hospitals (Bulletins et mémoires de la Société médicale des hôpitaux de Paris, June 18th) Dr. L. Galliard, of the Lariboisière, and Dr. Lasnier, a hospital interne, brought up this subject by presenting a patient, a consumptive woman, thirty-nine years old, free from syphilis, who bore on the anterior regions of both thighs, both arms, and the upper part of both forearms exceedingly numerous. almost confluent, lenticular blue spots. The pigmentation was seated in the derma and could not be made to disappear on pressure. They had observed the spots for a number of months, and the woman herself said that they had been there for several years. The tint was not quite so deep as that produced by tattooing with India ink.

The spots on the thighs were sharply bounded above by the fold of the groin, and they extended down to the region of the knee. They occupied exclusively the anterior, the inner, and the outer aspects of the thighs. Those on the front of the arms reached nearly to the shoulder. On the fore-

arms they were limited to the upper third of the anterior aspect. There were none anywhere else. In the regions occupied by the spots there were also many rounded, depressed cicatrices, of various sizes, but they were less numerous than the pigmented spots. They resembled the pits of smallpox. Nowhere were there any of the brown spots so frequently observed in morphinomaniacs.

The patient's story was that in 1897 she was admitted into the Hôtel-Dieu with pleurisy and intercostal neuralgia, and there received her first morphine injection. Soon afterward, unfortunately, she took service with some persons who were addicted to the use of morphine, and from them she acquired the habit of administering morphine to herself subcutaneously. She made the solution herself, using distilled water and cherry laurel water. It was never intentionally colored and she never noticed that it contained any solid matter in suspension. The depressed cicatrices occupied the sites of some of the injections which had caused a little irritation, followed by the formation of minute crusts, which she had scratched off, but there had never been anything like the formation of an abscess, although she had made no attempt at asepsis beyond providing herself with a new svringe occasionally.

Two other cases were mentioned as having been previously shown at meetings of the society, by M. Moutard-Martin and M. Thibierge, in both of which microscopic granules had been found in sections of the derma excised from the blue spots. Evidently, the authors remarked, the spots were not due to blood pigment, for that would long since have been absorbed. Particles of steel from the needles might have been detached and entered the punctures, or particles of lampblack might have been introduced with the injections. It was not stated whether or not the woman was in the habit of cleansing the needle of the syringe by subjecting it to the action of a flame. It can hardly be supposed that carbonaceous matter floating in the air can have been carried into the punctures in sufficient amount to give rise to the pigmentation.

GEORGE P. HUNTINGTON: AN APPRECIATION.

To have acquired, during one's lifetime, some measure of appreciation and praise has not usually been the good fortune of those who have presented new thoughts to the world. But we are pleased to note that a recent issue of Neurographs, a molest publication devoted to neurology and kindred branches, edited by Dr. William Browning, of New York, has been dedicated to the man who de-

scribed the disease now known as Huntington's chorea, Dr. George P. Huntington, whom, fortunately, we still have with us as an active physician.

The series of articles contained in the Neurographs are of special interest to neurologists, but the general practitioner can read them with pleasure and profit. Following an excellent portrait of Dr. Huntington, an editorial leads first to a biographical sketch of that author, by Dr. Winfield, of Brooklyn. This is followed by a reprint of the original description of the special form of chorea as given by Huntington himself in 1872. Strümpell, of Breslau, and Lannois and Paviot make two contributions to the subject, the former on the clinical character, the latter on the histology of the disease. Dr. Osler contributes a short historical note on hereditary chorea; Dr. Jelliffe makes a preliminary report on the historical aspects from the standpoint of the spread of the disease; Dr. Tilney traces the family history of a patient with Huntington's chorea back to 1596; Dr. Diefendorf gives the mental symptoms of the disease, and the editor, Dr. Browning, adds some very interesting biographies of others who have been interested in the subject, namely, Dr. Walters, Dr. Gorman, and Dr. Lyon. An excellent bibliography completes this appropriate recognition of an American practitioner.

Rems Items.

Mr. Henry Lomb, one of the founders of the Bausch & Lomb Optical Company, Rochester, N. Y., died on Saturday, June 13th, aged seventy-nine years.

The Medical Association of the Southwest, which embraces the states of Kansas, Arkansas, Oklahoma, Texas, and Missouri, will hold its annual meeting in Kansas City, Mo., on October 20th and 21st.

A Pasteur Institute in Burmah.—We learn from Science that a Pasteur Institute is to be established in Burmah. It will be some time, however, before the work on the building can be started.

A Brazilian Psychiatrical, Neurological, and Medicolegal Society has been organized with Professor J. Moreira as the first president. The society meets monthly in Rio de Janeiro at the National Hospital for the Insane.

Anniversary Day at the Methodist Episcopal Home for the Aged in Philadelphia, on Thursday, June 11th, resulted in the realization of \$5,000 for the running expenses of the home. The Mary Wagner Infirmary ward was opened.

The Training School for Nurses of the Samaritan Hospital, Philadelphia, held its commencement exercises on the evening of Tuesday, June 16th. Dr. Albert Robin delivered the address to the class. Nine young women received the diploma of the school.

Hospital of the Protestant Episcopal Church, Philadelphia.—At a stated meeting of the board of managers of this hospital, which was held on June 25th, Dr. Francis Wharton Sinkler, of Philadelphia, was appointed attending physician, in place of Dr. D. J. M. Miller, who resigned

Roof Playground at Roosevelt Hospital.-Plans have been filed for remodeling the south addition of the administration building of Roosevelt Hospital, in the centre of the hospital grounds, to provide a roof playground for the children under treatment in ward 6. The playground will be thirty-nine feet long and twenty-nine feet wide.

Contagious Diseases in Chicago.-During the week ending June 20, 1908, the following cases of communicable diseases were reported to the Department of Health:

diseases were reported to the Department of Health: Measles, 238; scarlet fever, 81; diphtheria, 56; tuberculosis, 55; typhoid fever, 20; whooping cough, 16; chicken pox, 10; smallpox, 4; miscellaneous diseases of minor importance, 5; total, 465.

The Boston Floating Hospital made her first trip this season on July 1st. The hospital will make trips daily, including Sundays, up to September 15th, and night trips are being arranged. Last year 74 trips were made; the average number of day patients on each trip was 36; the total number on all trips was 2,639. There were 366 permanent patients who stayed on an average of 17 days each.

The North Missouri Medical Society held its annual meeting in Moberly, Mo., on June 18th and 10th. Officers

meeting in Moberly, Mo., on June 18th and 19th. for the ensuing year were elected as follows: President, Dr. H. C. Given, of Kirksville; first vice president, Dr. W. L. Brossins, of Gallatin; second vice president, Dr. G. O. Cuppaidge, of Moberly; corresponding secretary, Dr. E. C. Gallison, of Moberly; recording secretary, Dr. O. McEwen, Of Salishyu; tressyurer, Dr. Pobert Haley, of Reol-fold Salisbury; treasurer, Dr. Robert Haley, of Brookfield.

The Health of Pittsburgh .- During the week ending June 20, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chicken pox, I case, o deaths; typhoid fever, 33 cases, 2 deaths; scarlet fever, 19 cases, o deaths; diphtheria, 8 cases, 2 deaths; measles, 129 cases, 4 deaths; whooping cough, 7 cases, o deaths; pulmonary tuberculosis, 27 cases, 18 deaths. The total deaths for the week numbered 137, in an estimated propulation of 103,230 corresponding to an annual death population of 403,330, corresponding to an annual death rate of 17.66 in 1,000 of population.

Merger of Medical Colleges.—Steps have been taken

towards the amalgamation of the Ohio and the Miami Medical Colleges of Cincinnati. It has been arranged that these two colleges are to continue during the next school year separately in their present buildings as departments of the University of Cincinnati, after which it is understood that both faculties will resign, and the two colleges united into one department of the university, with a new faculty to be selected by the university trustee

The Medical Society of the County of Wyoming, N. Y., will hold its regular quarterly meeting at the Silver Lake Sanatorium, Silver Lake, N. Y., on Thursday, July 16th. The programme will include a paper by Dr. William P. Spratling, of Sonyea, N. Y., on Epilepsy; a paper on Abortion by Dr. M. J. Wilson, of Warsaw; and a report of the recent outbreak of rabies at Gainesville by Dr. G. S. Skiff, of Gainesville. Dr. Mary T. Greene is president of the society and Dr. L. H. Humphrey is secretary.

Charitable Bequests.—By the will of Esther Tuttle Pritchard, Cook County Hospital, Chicago, receives \$1,000. By the will of Sir R. G. Reid, Queen's University, Kingston, Canada, the Hospital for the Insane at Verdun, the Montreal General Hospital, and the Alexandria Hospital will each receive \$5,000; the Western Hospital and the Victoria Order of Nurses will each receive \$2,500. By the will of William M. Ingraham Wesleyan University, Middletown, Conn. and Seney Hospital Brooklyn.

sity, Middletown, Conn., and Seney Hospital, Brooklyn, become reversionary legatees.

Instruction in the Care of Infants.-The Committee for the Improvement of the Condition of the Poor have established in New York twenty-three classes for the instruction of mothers in the care of infants, and in addition to this three consultation stations were opened on June 20th, where special visiting nurses will make their headquarters, and where volunteer physicians can go each day to give their services. These stations are situated at 216 East Second street, 176 West Sixty-third street, and 248 East 105th street. Seven new milk depots were also opened the city last week

The Mortality of Chicago.—During the week ending June 20, 1908, there were reported to the Department of Health of the City of Chicago 455 deaths from all causes, as compared with 509 for the preceding week and 607 for the year 1907. The annual death rate in 1,000 of population was 10.95, which is the lowest rate recorded in Chition was 10.95. which is the lowest rate recorded in Chicago for more than three years. The principal causes of death were: Apoplexy, 7; Bright's disease, 29; bronchitis, 8; consumption, 69; cancer, 36; convulsions, 3; diphtheria, 2; heart diseases, 33; intestinal diseases, acute, 37; measles, 2; nervous diseases, 12; pneumonia, 42; scarlet fever, 2; suicide, 8; violence (other than suicide), 30; whooping cough, 4; sunstroke, 1; all other causes, 127. Physicians Wanted for Public Institutions.—The State Civil Service Commission of New York announces that examinations will be held on July 25th to secure eligibles from which to fill vacancies in the position of State prison physician, with a salary of \$2,000 per annum, and in the position of woman physician, State hospitals and institutions, with a salary of \$1,000 to \$1,500 and maintenance. The last day for filing applications for these positions is July 18th. Full information and application forms for these examinations may be obtained from Mr. Charles S. Fowler, chief examiner of the commission, Albany, N. Y.

Lake Keuka Medical and Surgical Association.—The ninth annual meeting of this association will be held at Grove Springs, Lake Keuka, N. V. on Thursday and Friday, July oth and 10th. A splendid programme has been prepared, including twenty papers by prominent members of the medical profession, and ample arrangements have been made for the entertainment of members and their guests. Physicians who are not members of the society will be cordially welcomed, and ladies are also invited. The officers of the society are: President, Dr. Lewis Wheeler Rose, of Rochester; vice president, Dr. Charles C. R. Jennings, of Elmira; secretary and treasurer, Dr. H. B. Noble, of Pulteney; committee of arrangements, Dr. P. L. Alden and Dr. R. G. Lawrence of Hammondsport, N. Y.

Planning for the Reception Hospital for the Insane.

—Dr. Albert Warren Ferris, president of the New York State Commission in Lunacy, will spend the summer in Europe studying the methods used in conducting psychiatric hospitals, or psychopathic wards connected with general hospitals. Dr. Ferris is to perfect the plans for the psychiatric hospital, sometimes called the reception hospital for the insane, which is to be built in New York as soon as plans are formulated. He will visit Munich, Berlin, Vienna, and possibly Padua. Dr. Ferris will be accompanied by Dr. Adolph Meyer, director of the Pathological Institute of New York State Hospitals for the Insane, who was recently appointed director of the Henry Phipps Psychiatric Clinic at Johns Hopkins University.

National First Aid Association of America.—The

National First Aid Association of America.—The third annual meeting of this organization was held in Boston recently. Miss Clara Barton, the president of the association, was present at the meeting, but did not preside. Mr. Roscoe G. Wells, of Boston, acting treasurer, occupying the chair. The secretary's report showed a steady growth in the work of the association, and an increase in membership, there being branches of the organization in all but eleven states in the Union. About one thousand students are studying the association's work of giving first aid, and during the past year 62 classes have been conducted and 530 diplomas awarded. Since the association was organized in April, 1905, 178 classes have been formed, with a total enrollment of 3,428 students, and 1,538 diplomas have been awarded.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending June

The Health of Philadelphia.—During the week ending May 30, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Malarial fever, 2 cases, 0 deaths; typhoid fever, 28 cases, 4 deaths; scarlet fever, 54 cases, 1 death; chicken pox, 46 cases, 0 deaths; diphtheria, 52 cases, 7 deaths; measles, 416 cases, 13 deaths; whooping cough, 17 cases, 7 deaths; cerebrospinal meningitis, 2 cases, 2 deaths; pulmonary tuberculosis, 106 cases, 80 deaths; puemonary tuberculosis, 106 cases, 80 deaths; puemonary tuberculosis, 107 cases, 2 deaths; puemonary tuberculosis, 108 cases, 80 deaths; puemonary 12 cases, 30 deaths; erysipelas, 10 cases, 2 deaths; cancer, 22 cases, 30 deaths; tetanus, 3 cases, 1 death. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 6; diarrheea and enteritis, under two years of age, 25. The total number of deaths for the week numbered 474, in an esti-

mated population of 1,532,738, corresponding to an annual death rate of 16.01 in 1,000 of population. The total infant mortality was 97; under one year of age, 75; between one and two years of age, 22. There were 45 still births; 26 males and 19 females.

Officers of the State Medical Association of Texas.—At the annual meeting of the State Medical Association of Texas, held recently in Corpus Christi, the following officers were elected: President, Dr. H. W. Cummings, of Hearne; vice presidents, Dr. J. M. Inge, of Denton, Dr. A. Garwood, of New Braunfels, and Dr. A. M. Wood, of Galveston. Councilors: Second District, Dr. N. J. Phenix, of Colorado; Sixth District, Dr. H. J. Hamilton, of Laredo; Seventh District, Dr. J. C. Anderson, of Granger; Eighth District, Dr. W. A. McCamley, of Wharton; Ninth District, Dr. John T. Moore, of Galveston; Tenth District, Dr. D. S. Weir, of Beaumont; Twelfth District, Dr. G. S. McReynolds, of Temple. The next annual meeting of the association will be held in Galveston.

The Association of Medical Officers of the Army and

The Association of Medical Officers of the Army and Navy of the Confederacy held its eleventh annual meeting in Birmingham, Ala, recently. The membership of this association is composed of physicians who served in the Confederate army, and all Confederate veterans and their sons who are regular doctors of medicine are eligible to membership. The following officers were elected for the coming year: President, Dr. J. C. Abernathy, of Birmingham, Ala.; first vice president, Dr. W. F. Beard, of Shelbyville, Ky.; second vice president, Dr. E. D. Newton, of Athens, Ga.; third vice president, Dr. George M. Burdett, of Lemon City, Tenn.; fourth vice president, Dr. W. H. Barnes, of Homewood, Miss.; secretary, Dr. A. A. Lyon, of Nashville, Tenn. The next meeting will be held in Memphis, Tenn.

Vital Statistics of New York.—During the week ending June 20, 1908, there were reported to the Department of

Vital Statistics of New York.—During the week ending June 20, 1908, there were reported to the Department of Health of the City of New York 1,140 deaths from all causes, as compared with 1,219 for the preceding week and 1,426 for the corresponding period of 1907. Of the total number of deaths 571 were in Manhattan, 101 in The Bronx, 384 in Brooklyn, 53 in Queens, and 31 in Richmond. The annual death rate in 1,000 of population was 13,45, while the death rate in the corresponding period in 1907 was 17,36. The death rate in Manhattan was 12,99; in The Bronx, 16,09; in Brooklyn, 13,42; in Queens, 11,80; and in Richmond, 20.09. The total infant mortality for the week was 327; 268 under one year of age, and 59 between one and two years of age. There were 128 still births. Nine hundred and ninety marriages and 2,790 births were

recorded during the week.

The Edward N. Gibbs Memorial Prize.—The New York Academy of Medicine anounces that the sum of \$1,000 will be awarded to the author of the best essay submitted us competition for this prize. The subject is The Ætiology, Pathology, and Treatment of the Diseases of the Kidney. Pathology, and Treatment of the Diseases of the Kidney. Essays must be presented on or before October I, 1909; they must be in English; typewritten; designated by a motto or device; and each essay accompanied by a sealed envelope bearing the same motto or device, containing the name and address of the author. No envelope will be opened except that which accompanies the essay which wins the prize. The Academy reserves the right of withholding the prize ii, in the opinion of the committee, no essay is worthy of it. All communications should be addressed to the Committee of the New York Academy of Medicine on the Edward N. Gibbs Memorial Prize, 17 West Forty-third Street, New York.

The State Medical Society of Wisconsin.—The sixty-

The State Medical Society of Wisconsin.—The sixty-second annual meeting of this society was held in Minwaukee on Wednesday, Thursday, and Friday, June 24th, 25th, and 26th. The programme was a particularly good one, and included a series of clinics which were held during the meeting. The address in medicine was delivered by Dr. Walter B. Cannon, professor of physiology in the Harvard Medical School, and the address in surgery was delivered by Dr. E. Wyllys Andrews, professor of surgery in the Northwestern University Medical School. The annual banquet was held on Thursday evening, and there was a smoker at the rooms of the Milwaukee Medical Society on Wednesday evening. Officers for the ensuing year were elected as follows: Dr. Gilbert E. Seaman, of Milwaukee, president; Dr. H. B. Scars, of Beaver Dam, third vice president; Dr. C. S. Sheldon, of Madison, secretary; Dr. S. S. Ilall, of Ripon, treasurer.

Personal.-Colonel William C. Gorgas, chief sanitary officer of the Isthmian Canal Zone, had conferred upon him the honorary degree of Doctor of Science by Harvard University at the annual commencement held recently.

Dr. Glentworth R. Butler, of Brooklyn, has received from Wesleyan University, Middletown, Conn., the degree

of Doctor of Laws

Dr. William Osler, regius professor of medicine at Oxford University, has been selected as an independent candi date for the office of Lord Rector of Edinburgh University.

Dr. Francis E. Fronczak, assistant health commissioner of Buffalo, has been appointed a State lecturer on tubercu-losis by Dr. Eugene H. Porter, State Health Commissioner. Dr. John W. Goodsell, of New Kensington, Pa., will accompany Commander Robert E. Peary on his expedition in search of the North Pole. He will go as surgeon to the

Dr. Jacques Loeb, professor of physiology in the University of California, and Dr. Charles Sedgwick Minot, Stillman professor of comparative anatomy in the Medical School of Harvard University, have been appointed corresponding members of the Physicomedical Society of Vienna.

American Library Association.—The eleventh annual meeting of the American Library Association was held in Chicago, on June 1, 1908. The following programme was presented: President's address, on The History of the Terminology of the Disease Known as Graves's Disease, Basedow's Disease, Exophthalmic Goitre, etc., a Contribution to the Study of Medical Nomenclature, by Dr. George Dock, of Ann Arbor.; The Department of Medical Sciences of the John Crevar Library, by General A. C. Girard, of Chicago; The New York State Medical Library and the Education Building, by Dr. Albert Vander Veer, of Albany; The Use of Current Medical Literature in the Small Medical Library, by Dr. Carl E. Black, of Jackson-ville, Ill.; The Early Medical Profession in Canada, by Miss M. R. Charlton, of Montreal; The Development of Orthopædics as a Special Branch of Medical Literature, by Dr. H. Winnett Orr, of Lincoln, Neb. The annual dinner of the organization was held at the Union League Club on of the organization was held at the Union League Club on the evening of the meeting. The following officers were elected: President, Dr. George Dock, of Ann Arbor; vice president, Dr. John H. Musser, of Philadelphia; secretary, Miss Ada Bunnell, of Albany; treasurer, Dr. George D. Hershey, of Providence.

Campaign Against Tuberculosis in Brazil.-It is reported that the government of Brazil is preparing a campaign against tuberculosis. The present high rate of mortality from consumption explains why extraordinary measures against the disease are being taken. tality reports for Rio de Janeiro show that in 1905 out of a total of 14,660 deaths, 2,663 were due to pulmonary tuberculosis, as compared with 287 from yellow fever; in 1906, out of a total of 13,956 deaths, 2,649 were from tuberculosis and 42 from yellow fever; in 1907, out of a total of 13,014 deaths, 2,587 were from tuberculosis and 39 from yellow fever. Systematic work in sanitation has resulted in practically stamping out yellow fever in Rio de Janeiro, and with such success back of them the sanitary authorities feel that something can be done against tuberculosis. The new campaign involves the initial expenditure of \$1,250,000, and while twenty-six cities are included in the plans, attention will be directed first to Rio de Janeiro plans, attention will be directed first to kilo de jainting and no modern means for combating the disease will be neglected. The principal features of the plan are: The compulsory reporting of every case of tuberculosis to the sanitary authorities, the complete assumption of charge of all cases of tuberculosis by public authorities, in which industrial cases are expected from the public and patients. fectious cases are separated from the public and patients supported by the public; the establishment of hospitals, with complete isolation, for tuberculosis infected invalids, and of hotels and boarding houses, agricultural colonies and sanitaria for those not invalid; the absolute refusal of admission into Brazil of any person or animal having tuberculosis; the inspection of all foods and materials likely to carry bacilli of the disease, with power to destroy anything infected; and the betterment of food, housing, and other conditions of life for the large mass of the population in which tuberculosis is raging, for the prevention of the disease, by fortifying the people against it vention of the disease by fortifying the people against it by improving their general health.

Surgical Shock.

By GEORGE CRILE.

Achondroplasia

By William N. Bullard and Arial W. George.
Alphamonobrom-Isolvalerylurea. A New Nerve Sedative and Somnifacient. By William Henry Porter.
The Local Treatment of Acute Inflammations of the Throat from the Standpoint of Pathology,
By J. L. Goodale.

I. Surgical Shock .- Crile remarks that the depression in the majority of the traumatic cases is due to both shock and hæmorrhage. In the absence of a clear history it is not easy to determine their relative importance. Fortunately, the treatment of each is virtually the same. In traumatic cases demanding operation, should one operate immediately or should one wait for reaction? This question may be answered either way. Immediate operation may be performed if the operative field can be blocked by cocaine, thus preventing further shock, as, for example, the lower extremities by spinal anæsthesia, the arm by blocking the brachial plexus, or if, says the author, the patient is treated by a transfusion of blood. On the other hand, if these circumstances do not exist, it is, in his opinion, better to await reaction. At all events, while operating on such cases, the nerve trunks supplying the field in question should, whenever possible, be blocked, even when general anæsthesia is administered. In these cases, in which sensitive tissue in quantities is mangled, especially in the compound fractures, when the soft parts are no longer supported, the greatest gentleness must be exercised. The principal causes of collapse coming to the attention of the surgeon arise from anæsthetic accidents, asphyxia, reflex inhibition, and hæmorrhage. The consideration of collapse presupposes cases of suspended animation. We must also consider resuscitation of parts of the brain. Total anæmia of certain essential parts of the central nervous system is safely endured but little beyond six minutes. There is a marked difference in the length of time that the various tissues and organs of the body can endure total anæmia with safety. The bones, tendons, skin, muscles, the cardiovascular system, the various organs and glands, and the central nervous system show an individual resistance to anæmia. According to the author's experiments on animals and clinical observation, every effort should be made not only to sustain, but, if possible, to increase, the general blood pressure in cases of increased intracranial pressure so as to make certain of the necessary circulation during the entire operation. Shock and hæmorrhage here have a specialized significance.

4. The Local Treatment of Acute Inflammations of the Throat from the Standpoint of Pathology.—Goodale offers the following hypotheses: I. In a beginning tonsillitis antiseptic applications may perhaps be used with benefit, and their effect, if any, will be to abort the local infection. If the disease is not checked at the outset by the sterilization of the parts, but if it proceeds to the formation of white spots in the crypts with systemic involvement, further application of antiseptics may not only be useless but harmful. It would appear possible that antiseptics may retard convalescence in two ways; first, by diminishing the number of bacteria in the crypts which are generating toxine, and consequently prolonging the period required for the formation of the requisite amount of antibodies; second, by their destructive action upon the tissue cells and phagocytic leucocytes of the host. 2. Forcible application of antiseptics may be followed by increased fever and cervical adenitis, indicating heightened absorption of toxine into the system. This phenomenon may be compared to the depression which follows the injection of too large a dose of vaccine in cases undergoing opsonic treatment. 3. In certain cases where acute tonsillitis appears to be aborted by local antiseptics, inflammatory manifestations may follow after a day or two in the neighboring regions, and last for a number of days or several weeks. Here the possibility is suggested that the checking of the tonsillitis checked also the establishment of immunity, and that for its final accomplishment a longer period of growth of the organism upon the membranes of the nose, larynx, trachea, or bronchi was necessary. In this connection we may recall the protracted duration of nasal diphtheria, as compared with the relatively brief time occupied by the pharyngeal disease.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. June 27, 1908.

Hyperæmia,
Local Applications in Surgery.
The Calmette Ocular Reaction to Tuberculin,
By Harry C. Parker.
Colles's Fracture, with a New Theory of its Mechanism,
By Leonard W. Ely.

I. Hyperæmia.—Binnie reminds us that pain in an inflammatory lesion seems to be due to irritation by toxines, and especially to the high specific gravity of the inflammatory exudates. Hyperæmia properly produced destroys or dilutes the toxines and dilutes the exudates. The tense swelling is due to an exudate of high specific gravity—the tension prevents the inflow of blood to the part and the escape of diluting sera from the vessels, and when the tension is removed fresh blood flows into the part and relief is obtained. If pus is present it is evacuated through a comparatively small cut or puncture. The suction of the cupping glass will notably aid in the removal of the pus. A suitable cup which completely covers the lesion is applied. Suction is produced by means of a rubber bulb or a syringe. The suction must be strong enough to produce a red swelling of the part. If the swelling becomes blue the suction is too powerful. The same is true if pain or paræsthesia is occasioned. The suction is kept up for five minutes, the cup is removed for three minutes and reapplied for five minutes, etc. This alternation of five minutes of suction and three minutes of rest is persisted in for about forty-five minutes daily. The patients quickly learn the correct degree of suction to apply and soon can carry out the treatment better than can the surgeon. The suction exerted brings an increased quantity of the vessels; thus an unusual amount of the active protective material is brought into the place where it will do most good. The suction must be sufficiently strong to produce this condition, but not strong enough to cause stasis of the blood in the part. There must be an increased inflow and only a slightly decreased outflow of blood in order that the maximum amount of the active fighting forces may be present during the whole period of suction. The periods of rest permit the escape of blood from the part, and thus when the suction is once more applied an entirely fresh supply of fighting material is obtained.

3. The Calmette Ocular Reaction to Tuberculin.—Parker concludes from his observations that the Calmette ocular tuberculin test is of as great diagnostic importance as any other single test. positive reaction is indicative of a tuberculous focus sowewhere in the body. The test is uncertain in patients under two years of age, in whom the cutaneous test of von Pirquet is most certain. The test fails in advanced cases of tuberculosis, but there is little need of it here for diagnostic purposes. The initial instillation should be preferably under one per cent. strength, in order that severe inflammatory conditions may not follow its use. If necessary to make the second and stronger test the instillation should be made in the eye not previously used. The consensus of opinion seems to be against using the test in an eye not wholly normal. After complications have occurred from the use of the test, but these have entirely cleared up in a varying length of time. These conditions are not so frequent when the initial test in made with a solution under one per cent. in strength. Recent investigations have shown a greater number of ophthalmic affections due to tuberculosis than formerly supposed, and in the Calmette reaction we have a simple means of distinctive diagnosis which should be thoroughly tried. The ocular reaction is especially valuable for ascertaining the tuberculous nature of cases of phlyctenular keratitis and conjunctivitis, episcleritis and scleritis, chronic iritis and iridicyclitis, interstitial keratitis, and choroiditis. A one per cent. solution of Koch's "old" tuberculin is nearly as good as the Calmette solution for diagnostic purposes.

 Method of the Spread of Yellow Fever, By Colonel W. C. Gorgas. An Intradural Tumor of the Optic Nerve Removed by the Kronlein Method,

By Frank Van Fleer.

Influenza: Its Diagnosis from a Morphological Standpoint in Stained Specimens of Sputum,

Ry Grapes W. Styles

By George W. Stiles.

Several Cases Illustrating Liver Symptoms in Cardiac By Louis Faugères Bishop. Adverse Suggestion, By Austen Fox Riggs.

The Relation of Pleurisy to Pulmonary Tuberculosis,
By HENRY S. GODDALL 1. Method of the Spread of Yellow Fever .-

Gorgas describes the work done in exterminating yellow fever in Havana, Cuba, and on the Isthmus of Panama. It took eight months to get rid of fever in Havana, but sixteen on the Isthmus of Panama, although the same methods were used in Havana as on the isthmus. But it must be remembered that sanitary work was done two and one-half years in Havana before yellow fever disappeared, while in Panama nothing had been done before. Colonel Gorgas explains the difference in the fol-

lowing way: Take a city such as Panama, in which normally all the conditions are perfect for the perpetuation of yellow fever. Under these conditions, we will say we have one hundred stegomyias to the square yard. When a case of yellow fever occurs the patient is always bitten by mosquitoes during the infective period, and, therefore, always leaves a number of infected stegomyia mosquitoes which can convey the disease to nonimmunes present. This has been the mosquito condition of Panama since the world began. Now, if we reduce those mosquitoes to fifty to the square yard, the yellow fever patient will still be bitten, but not by so many mosquitoes, and therefore there will not be so many infected mosquitoes left. We would still have yellow fever if nonimmunes were present, but not so extensively. We reduce them still further to twenty-five. A smaller number of stegomyias bite the yellow fever patient, and we have fewer infected stegomyia mosquitoes, but still some, and if nonimmunes are present, we have a slight epidemic. We go on still further with our work and reduce them to fifteen. The same results follow, only the epidemic is still milder as to numbers. We go on with our work and reduce them to ten per cent, of the original number. The probabilities are that at this stage if we introduce the vellow fever patient the patient is not bitten, we get no infected mosquitoes, and yellow fever abruptly disappears. While it is possible with ten mosquitoes to the square yard for one mosquito to become infected and give yellow fever to some other nonimmune in the house, it is not probable that this second yellow fever patient will infect a second stegomyia. He is, therefore, inclined to believe that a certain number of stegomyia mosquitoes are necessary for the propagation of yellow fever, and ordinarily in yellow fever countries this number is largely exceeded; that our work goes on reducing the number without showing much results; and that, after awhile, our work reduces the number below this spreading point, when yellow fever abruptly ceases. We should, therefore, keep the mosquitoes below this number, which he calls the yellow fever point. and no matter how many nonimmunes or how many cases of vellow fever are introduced, vellow fever cannot spread.

3. Influenza. — Stiles reviews one hundred cases of influenza, and comes to the conclusion that microscopical examinations of sputum from cases manifesting general respiratory symptoms of disease are absolutely necessary. No matter what the previous diagnosis may have been from the symptomatology alone, further light on the condition of the patient may be had from a microscopical study of the sputum. Valuable information may be obtained from a brief study of well stained specimens of sputum from suspected or complicated cases of influenza. A few cases resembling tuberculosis may be due to infection of influenza bacilli alone or to a mixed infection of the two organisms.

4. Several Cases Illustrating Liver Symptoms in Cardiac Disease.—Bishop remarks that three cardinal symptoms of heart disease are dyspnœa, enlargement and tenderness of the liver, and dropsy. Enlargement and tenderness of the liver is an important indication of the general disturbance of the circulation that results from failure of the heart.

The venous stagnation results in swelling and tenderness of the liver, and the liver affords in this way an important indication of the progress of cardiac disease. The tenderness is often greater in acute cardiac failure than in old cases. An enlargement of the liver during this condition may be considerable, and this disturbance of the liver leads in some cases to a slight degree of jaundice. So valuable a symptom is tenderness and enlargement of the liver that, in picking out the heart cases in hasty hospital rounds when first on duty with upwards of a hundred patients to review in a short time, he has made it a practice to palpate the liver before using the stethoscope. In the absence of enlargement and tenderness of the liver an urgent uncomplicated heart case has hardly ever been found, if the condition has existed several days.

5. Adverse Suggestion.—Riggs remarks that to avoid the evils of adverse suggestion and to take advantage of all the good inherent in favorable suggestion is clearly the duty of every physician. To accomplish this with complete success, it is necessary that one should always keep vividly before one's mind the following facts: The ultimate object of all medical work, whether clinical, experimental, chemical, or whatnot, is relief of suffering. Suffering is a mental process and stands in relation to bodily ills not only as effect, but also as cause. Every patient is suggestible, and is, therefore, a highly individualized psychological as well as a physiological problem, and should be studied and treated as such. Therefore, it is obviously as necessary that the physician should acquire a knowledge of psychology and of its application to medicine as it is that he should be familiar with physiology, pathology, or materia medica, for they are all intimately correlated component parts of the one great

entity—the healing art.
6. The Relation of Pleurisy to Pulmonary Tuberculosis.—Goodall states that a very large percentage of cases of apparently primary sero-fibrinous pleurisy may be demonstrated to be of tuberculous nature by laboratory methods, provided the investigator is sufficiently proficient with the method employed. He finds that in various series of cases that have been followed for some years after the serofibrinous pleurisy, a large number show tuberculosis, the figures varying from fifteen per cent. in Cabot's series to 82.6 per cent. in the series of Fiedler. While it must not be forgotten that pleurisy with effusion may accompany lobar pneumonia or may be caused by the pneumococcus without pulmonary involvement, and that it may also result from streptococci, staphylococci, and other microorganisms, as well as from cancerous disease: and while we must also remember that serous fluid in the pleural cavity may be merely a transudate due to renal or cardiac disease, we must nevertheless be convinced that all these causes together are responsible for only a minority of the cases of so called idiopathic serofibrinous pleurisy, the majority being cases of tuberculosis of the pleura, and to be treated accordingly. Those of us, says the author. who have opportunity to gain special experience in tuberculous work so frequently see pulmonary tuberculosis developing within a year or two after an attack of serofibrinous pleurisy, recovery from

which had apparently been good, that we are ready to accept the conclusion that the great majority of initial serofibrinous pleurisies are of a tuberculous nature. From this it follows that when called upon to treat a case of apparently primary pleurisy with serous effusion, it is the physician's duty to bring to bear upon it as many methods of determining its nature as possible, and that only when there is positive evidence of a cause other than the tubercle bacillus should he discharge the case. In all serofibrinous pleurisies the absence of a demonstrable positive nontuberculous cause should be accepted as a presumptive evidence that the case is really one of tuberculous pleurisy, and the case should be watched and handled as a case of incipient tuberculosis for a period of not less than two years. Signs of pulmonary tuberculosis not infrequently are found first at the upper part of the lung opposite to the side on which the pleurisy occurred. For this reason the entire chest must be investigated. By following this course, while we may perchance exercise control in an occasional case where control is not needed, we will certainly pluck many and many a case from the grasp of the Great Destroyer and prolong many useful lives that would otherwise follow the downward course so common in untreated or tardily treated cases of tuberculosis. This is the more true because the type of tuberculosis following pleurisy with effusion is usually not very violent, and we may therefore expect very satisfactory results from suitable prolonged supervision and treatment.

Recovery, By R. MANWARING-WHITE. The Treatment of Fractures, By H. T. GRAY.

Thoracic Aneurysm. - Drummond holds that aneurysm of the thoracic aorta is undoubtedly a syphilitic disease, though aortic strain from hard work where the tissues are already degenerated by alcoholic excesses must certainly predispose. A strong alcoholic history was obtained in more than forty per-cent. of the writer's cases. Of 225 cases of aneurysm, 170 were sacculated, thirty-nine fusiform, and seven dissecting. In much the larger proportion of cases the aneurysm occurs in the transverse portion of the arch of the aorta. As regards rupture, the trachea and the pericardium are the most vulnerable structures, whilst rupture into the left pleura, left bronchus, and superior rena cava and œsophagus are of comparatively frequent occurrence. The usual age at which thoracic aneurysm develops seems to be from thirty-five to sixty years. Only occasionally is it met with in advanced life, and then it is but rarely of the sacculated form. Aneurvsm is rare among women, it occurring eight times more frequently in men. The chief physical signs and symptoms of thoracic aneurysm, in the order of their relative frequency,

are as follows: Pain. A striking characteristic of aneurysmal pain is that it is nearly always complained of at night. The patient goes to bed feeling comfortable, and is awakened by the pain, for the relief of which he alters his position, sitting up, or even walking about the room. In many cases there are two distinct types of pain-one anginal, worse through the day, aggravated by exertion, and relieved by resting; the other, the true aneurysmal pain, worse at night, and relieved by change of posture. Anginal pain is often referred to both arms. The position of the aneurysmal sac may frequently be diagnosticated from the distribution of the pain. Two aneurysmal sites in which pain is a rare feature are the sinus of Valsalva and the posterior part of the descending transverse arch. Sacs springing from the lower part of the front of the ascending arch produce pain referred to the pericardium; later it is referred to the right shoulder. The higher on the arch, the higher the location of the pain, and the more the sac approaches the posterior part of the inside of the ascending arch the greater is the tendency for the pain to pass towards the right. Posterior aneurysms tend to affect the right shoulder more frequently than the left, whilst the reverse is the case with those springing from corresponding positions on the front of the arch. Cough. This is often present for some time before any other symptoms manifest themselves. It is usually loud, in-effectual, and paroxysmal. Later on it assumes a ringing metallic character, and later the husky "leopard growl," characteristic of pressure on the trachea. Pulsating tumor. This, though a very frequent physical sign, is not always easy to distinguish. Alteration of the second aortic sound. This is detected by means of the stethoscope; this is loud and voluminous, and is best heard away from the aortic valves, practically over the sac at the point where it approaches nearest the chest walls. equality of pupils. This is a common symptom, and is most frequent in cases of sac arising from the transverse portion of the arch. Inequality of pulses. This sign may be difficult to detect, and its recognition will be facilitated by instructing the patient to inspire and expire slowly and deeply. Dysphagia This seldom amounts to serious obstruction. It may affect both fluids and solids, but more frequently the latter. Paralysis of the vocal cords. This is not always attended by hoarseness, so that a careful laryngoscopical examination should be made in every case. The abductors are first affected and later the adductors which only become paralyzed after considerable pressure on the recurrent. Tracheal tugging. This is detected by gently grasping and attempting to elevate the cricoid cartilage, when a jerk can be felt synchronous with the cardiac systole. Tracheal whiff. This may be heard either over the trachea or in the mouth. It is usually systolic, but may be double, and is usually heard best when the patient is expiring slowly after a deep inspiration with the mouth wide open.

3. Myalgia.—Keith restricts the term myalgia to pain in the muscles caused by strain. It often simulates acute articular rheumatism, acute inflammatory maladies, and visceral disease, such as appendicitis. But the previous history, the normal temperature and pulse, and the beneficial effects of

rest, usually suffice to make the diagnosis clear. It must be borne in mind that the pain may suddenly make its appearance some time after the exciting cause has ceased to be in action. The most essential point in treatment is to place the painful muscle or muscles in the most restful position possible. In severe abdominal cases rest in bed with morphine may be necessary. In less severe forms a stout abdominal belt may be all that is required. Investigation should be made as to any existing cause of debility, such an anæmia, leucorrhœa, oral sepsis, etc. Myalgia occurs either in robust patients who have undergone unusual strain, or in the debilitated in the course of their usual work.

4. Infant Binders .- Waring has become deeply impressed with the vast amount of harm and suffering caused by the discomfort and the constriction of the abdomen and thorax due to the use of infant binders. Among the results and conditions which may result from binder compression are the following: I. Discomfort. This may be so great as to cause restlessness, crying, and loss of sleep. Typical outward signs are lividity of the face, dilated temporal veins, and clenched fists. 2. Vomiting frequently results from undue constriction, being enhanced by flatulent distention, and being more of the nature of a regurgitation. 3. Inguinal and umbilical hernia. The increase in both the intraabdominal and intrathoracic pressures caused by the binder throws the whole pressure on the inguinal region, and leads to the occurrence of inguinal hernia. The frequent slipping upwards of the binder uncovers the umbilicus, and thus tends to produce umbilical hernia. 4. Prolapsus ani, following hæmorrhoidal distention of veins. 5. Thoracic deformities, due to arrest of the growth and development of the chest. Happily, such a contracted chest may subsequently expand to normal proportions. Thoracic constriction in pulmonary disease is obviously most harmful, as it hampers respiratory movements and impedes free entry of air and oxygenation. 7. The cerebral circulation may be so disturbed by severe constriction as to give rise to convulsions. 8. Asphyxia due to "overlying" by the mother, may be rendered fatal if the child has on a tight binder, constricting the movements of the chest.

2. Myoma of the Uterus.—Martin, in his second Ingleby lecture, takes up the treatment of myoma uteri. Nonsurgical treatment. Ii a patient has only a small myoma which is not growing, and not causing pain, severe hæmorrhage, or interference with her health or comfort, an operation should not be advised. But careful watch should be kept over the case. A fibroid which is not actively growing may yet vary in size from time to time, being larger and more vascular just before the period and smaller after it. So that all examinations should be made at the same corresponding time each month. A patient with a troublesome myoma should rest as much as possible, and should stay in bed during the period. If there is a tendency to flooding, the foot of the bed should be raised twelve inches or more. All strain and fatigue and all violent physical exercise should be avoided as tending to bring on sudden and alarming bleeding. Suitable measures should be taken to prevent conception. Sexual intercourse is very apt to start hæmorrhage in all cases of polypus and most submucous fibroids, and should then be forbidden. No corsets should be worn, as they tend to press the tumor down into the pelvis, and keep up a condition of chronic venous congestion by obstructing the abdominal veins. The wearing of a light abdominal belt is sometimes beneficial, especially where the tumor is of large size. It is sometimes useful to support the uterus from below by means of a pessary. Drug treatment is unsatisfactory, and resolves itself into the alleviation of symptoms. Of these, hæmorrhage is the most important. Ergot is our chief remedy for the control of the bleeding and is often of great value. But beyond checking the bleeding, its effect on the myoma is not good. The uterine contractions which it excites tend to convert an interstitial fibroid into either a subserous or submucous one, and the tendency to flooding is increased. The prolonged use of ergot predisposes to degeneration and necrosis of the fibroid by interfering with its blood supply. Hydrastis is often prescribed with ergot. Calcium chloride increases the coagulability of the blood and is often of undoubted service. Bromide, iodide, and chlorate of potassium have all failed to be of service in the writer's hands. In cases of anæmia care should be taken in ordering iron as a tonic, as it may excite dangerous hæmorrhage. The organic preparations are safer than the inorganic. The bowels should be kept well open, as straining at stool may cause hæmorrhage, and also fibroids frequently cause hæmorrhage from pressure. Plugging the uterus and vagina is of great help in controlling dangerous bleeding. Electrolysis as a means of treatment has been given a careful trial and has been abandoned as futile and dangerous. Surgical treatment. Among the contraindications to operation are: (1) Where the tumor is smaller than an orange, is causing no symptoms, and is not growing; (2) where the patient is past the change of life and the myoma is quiescent and causing no trouble; or (3) where the patient is gravely ill from some other condition, such as pulmonary tuberculosis, heart disease, or nephritis, which will of itself prove fatal before long. On the other hand, an operation is called for: (1) Where there is severe bleeding, uncontrolled by rest and ergot; (2) where there is rapid or persistent growth of the tumor; (3) where there are signs of degeneration, necrosis, or malignant disease; (4) in many cases complicated with pregnancy; (5) in cases complicated with gross lesions of the ovaries and tubes; (6) where there are marked symptoms of pressure on the urinary organs; (7) where the tumor is very large and from its great bulk and weight becomes a burden; (8) in some single women where the tumor, from its size, leads to unfounded suspicions of pregnancy and causes the patient much unhappiness; and (9) in cases of sterility due to the presence of a myoma which can be removed without sacrificing the uterus. The vaginal operations for myoma may be classified as follows: Curetting. This should be performed after the removal of a fibroid polypus or a submucous myoma, in order to cure the accompanying endometritis. It is seldom of more than temporary benefit, and is dangerous in cases complicated with pyosalpinx or ovarian abscess. Removal of polypi. These should be removed as soon as discovered, beng either twisted off with volsella, or by crushing and ligating the pedicle. Vaginal myomectomy. This is the operation par excellence for the removal of submucous growths, which are usually single. Ligature of the uterine arteries has never found much favor in England. Vaginal hysterectomy is the best operation to perform in cases of small myomata, as it removes the whole of the disease, does not involve an abdominal scar, and the risk to life is but moderate. It may be very dangerous if the uterus is larger than a three months' pregnancy, if it be fixed by adhesions, or if the case be complicated by pyosalpinx or ovarian abscess. The more important abdominal operations for myoma fall under three headings: (1) Removal of the uterine appendages, where the tubes and ovaries are taken away, but the uterus is left behind. This operation has been abandoned. (2) Hysterectomy, where the tumor with most or all of the uterus is removed. This may be intraperitoneal or extraperitoneal. (3) Abdominal myomectomy, where all the tumor itself is removed but the uterus itself is saved. This is the operation of the future. The writer has performed it seventy-three times, with one death; low as that death rate is, it should be reduced to zero.

1. Prophylaxis of Syphilis in the Army By C. H. Lemoine. By R. Romme. Apropos of Infusions of Oxygen,

1. Prophylaxis of Syphilis in the Army.-Lemoine reprints the figures given by Fournier after a statistical study of the morbidity in the different European armies showing the consequences of prostitution. The German army showed a morbidity of 5.7 per 1,000, the Belgian 6.7 per 1,000, the French (including the troops in Algeria) 6.8 per 1,000, the Bavarian 9 per 1,000, the Russian 12 per 1,000, the Italian 13 per 1,000, the Roumanian 16 per 1,000, the Austrian 19 per 1,000, the English, metropolitan troops, 75 per 1,000, colonial troops, 139 per 1,000. The minimum was found in Germany, the country in which prostitution is most severely regulated, the maximum in England, in which prostitution is not

regulated. The natural conclusion from these figures is in favor of regulation of prostitution as a means of reducing the number of syphilitics.

r. Spontaneous Sporotrichosis of the Dog. Subcutaneous Gumma, Granular Peritonitis, and Hepatic Gumma, By Gougerof and Caraven.

By MAURICE LETULLE. Lumbar Appendicectomy, By F. LEGUEU.

- Spontaneous Sporotrichosis in Dogs.— Gougerot and Caraven describe very elaborately the lesions present in three dogs, all of the same litter, that suffered from sporotrichosis which had not been artificially induced. The course of the disease in each dog is described, and after that the histological condition of the tissues and organs. Finally they state that this proves the spontaneous occurrence of sporotrichosis in dogs, and that this disease may appear in at least two forms, one marked by suppurating cervical gummata and diseases of the joints. This form is sometimes fatal, sometimes curable, but leaves behind it rhachitic, bony deformities, and entails a retardation of development. The other, much more serious, is characterized by a granular peritonitis, hepatic gummata, and pulmonary involvement. The discovery of spontaneous sporotrichosis in animals explains one manner in which the diffusion of the Sporotrichum Beurmanni takes place, and suggests the possibility of transmissibility from the ani-
- 3. Lumbar Appendicectomy. Legueu describes in detail the removal of the appendix through an incision in the lumbar region, an operation which he thinks is preferable to the usual one through the abdominal wall.

 A Method for the Disinfection of Stomach Tubes in Daily Practice,
 By E. Fuld.

The Connection between Diseases of the Nose and of the Nasopharynx with Those of the Eye (Concluded),
 Criminal Abortion,
 By A. Onodi. By Hugo Marx.

2. Substances in the Blood Serum Which Promote Phagocytosis.—Meyer says that the opsonin of the normal serum has the same structure as the bacteriolysin, i. e., it is made from two components, one thermostabile, the other thermolabile and acting as a complement. It may be that the amboceptor and complement are loosely united, or that the union between bacteria and amboceptor can be easily dissolved. Further investigations are necessary to determine whether, on account of this behavior, an identification of the opsonin with the bacteriolysin is inadmissible.

5. Treatment of Exophthalmic Goître with the Antithyreoidin of Moebius.—Baumann states that he effected a complete cure of a well marked case of exophthalmic goitre in a woman, twenty-seven years of age, by the administration of the antithyreoidin of Moebius. Eight drops were given three times a day at first, then ten drops three times a day. Only thirty c. c. was given, and the

treatment lasted only three weeks.

7. Disinfection of Stomach Tubes.—Fuld recommends to place the tube in fifty per cent, glycerin, heat it to a temperature of 70° C., and maintain this temperature for twenty minutes. He alleges that this surely kills all pathogenic germs, is a convenient precedure, and does not injure the tubes.

8. Connection between Diseases of the Nose and Nasopharynx and Those of the Eye.—Onodi deals in his long paper wholly with the ocular symptoms and diseases produced by inflammation of the

accessory sinuses of the nose.

9. Criminal Abortion.—Marx makes the interesting statement that criminal abortion and child murder have a certain inverse ratio to each other. In the large cities, where the opportunities are greater, criminal abortion is the more common, while in the country, where such facilities are more lacking, child murder is proportionately more common.

Proceedings of Societies.

THE AMERICAN GYNÆCOLOGICAL SOCIETY.

(Concluded from Vol. LXXXVII, page 1265.)
The Intrapelvic (Supplied) vs. the Ardoninal meti

THE INTRAPELVIC (SUBPUBIC) VS, THE ABDOMINAL METH-OD OF DEALING WITH MECHANICAL OBSTRUCTION TO DELIVERY.

Dr. E. REYNOLDS, of Boston, stated that if extraction was possible in a given case without hard pulling, Cæsarean section would not be indicated. In cases in which a severe labor was clearly probable, the Cæsarean section was indicated. A low maternal mortality was the prime consideration, and should determine the choice of operative method. In the Cæsarean section at the beginning of labor the maternal mortality should not exceed one per cent. In neglected labors the maternal mortality rate from this method increased rapidly. In any case, the mortality was influenced by the condition of the mother when the operation was performed. The risks for the child were greater than for the mother. In neglected labors the Cæsarean section should be limited to cases in which delivery by the natural route was not possible. The mechanical

difficulties likely to be encountered in a given case could usually be predicted. Cases of difficulty by the natural route meant danger for the child and disease for the mother. The results of primary Cæsarean section in multiparæ could be foretold with considerable accuracy, but with less accuracy in primaparæ, for the injury to the soft parts in the latter was a matter for careful consideration. With soft parts which were not readily dilated, the prospects were often unfavorable for both mother and child. In general, it might be said that intrapelvic operations were suitable for strong, young primaparæ, and the Cæsarean section for old primaparæ. The Cæsarean section was an operation which was not usually within the province of the general practitioner.

Dr. R. C. Norris, of Philadelphia, believed that modern results of elective Cæsarean section justified the extension of the limit of the absolute indication. If the conjugata vera measured no more than 71/2 to 8 centimetres, the indication for section was absolute. Cases in which a section would probably be required should be carefully examined and studied. The high mortality from section in neglected labors was due to infrapubic sepsis. In examining a patient the relations of the fœtal head to the maternal brim should be ascertained by suprapubic pressure, the bony prominences should be noted, and the condition of the soft parts ob-The external measurements were not always of great importance, but the reverse was true as to the height of the sacral promontory and the symphysis pubis. The mortality and morbidity in all cases were influenced by the duration of the first stage of labor as well as by the conditions of delivery. It was not necessarily true that in any given case an abdominal operation would be tolerated as well as a subpubic one. In the majority of cases, the patient should have the benefit of the test of labor, but the duration of this test should be short, after which the question as to the form of operative procedure should be considered. More favorable than Cæsarean section was the induction of labor from two to four weeks before term.

Dr. E. H. GRANDIN, of New York, preferred the premature induction of labor in the lesser degrees of contraction, if the head could be made to enter the brim: otherwise the Cæsarean section, with the consent of the parents. Version was still an approved operation with the speaker in cases in which dilatation was proceeding slowly; it was preferable to the high application of the forceps. Symphysiotomy rather than pubiotomy was recommemded for cases in which version was impracticable. If the birth canal was obstructed by tumors, whether solid or cystic, they should be removed early in the labor. The tentative use of the forceps was not advisable. Abdominal Cæsarean section was advocated when the conditions were unfavorable for other operative procedures. The vaginal Cæsarean section was indicated in cases in which there was toxæmia or hæmorrhage, but manual dilatation and forceps delivery was to be preferred to that operation.

Dr. B. C. Hirst, of Philadelphia, was an advocate of the induction of labor during the ninth month in cases in which normal labor was improbable. This was preferable to publiotomy or symphysiotomy. Cæsarean section was advisable under favorable conditions within twenty-four hours of the time for labor, but it was allowable even after labor had progressed for hours, especially if no other operation had been attempted. The fœtal mortality of induced labor amid favorable surroundings was less than ten per cent. The speaker's technique for Cæsarean section, with careful preparation of the vulva, vagina, and abdominal wall, was described.

Dr. A. Lapthorn Smith, of Montreal, believed that Cæsarean section had reached such a degree of perfection that it should have no more mortality for mother or child than normal labor when performed as an operation of election and by an experienced operator. This could not be said concerning the prolonged use of the forceps or of even

the best of the subpubic methods.

Dr. E. P. Davis, of Philadelphia, urged the necessity of examining patients before labor began, but admitted that it was not always practicable. Owing to the variety in the different classes of patients, the element of chance would always be significant. In hospital cases in Europe, the consideration for the child was often not so great as that for the mother; this was especially true with unmarried women. This distinction was a bad one, and should not obtain. A child of such parentage might develop into a good and useful citizen. Doctors were often at fault in hurrying labor by instrumental means, especially in primiparæ. As to the Cæsarean section, its mortality, even in the neglected cases, was not necessarily high, especially if the forceps operation or version had not been attempted; when it was employed as a last resort, the mortality rate would always be high, and the same must always be true when the Porro operation was performed. The possibilities of the suprasymphysial operation must not be forgotten as an alternative to the Cæsarean section.

Dr. F. PFANNENSTIEL, of Kiel, Germany, stated that the German law required the consent of a patient or those who were responsible for her before a serious operation was performed, but, having obtained this consent, one could do what seemed indicated. In cases of moderately contracted pelvis, he would recommend nebotomy or symphysiotomy, reserving Cæsarean section for the higher degrees of contraction. Pelvimetry he considered essential, especially the mensuration of the conjugata vera. Löhlein's measurements, both for the conjugata vera and the transversa were approved.

vera and the transversa, were approved.

Dr. R. A. Murray, of New York, thought the weak point in the obstetric teaching of the day was the failure to impress upon students the lesson that Nature should be given a chance before interference was attempted. Practitioners were constantly making complications by interference with normal labor, sufficient time not being allowed for moulding and the mechanism of labor. He was almost in favor of abandoning version and the high forceps operation upon the unengaged head and for primaparæ. He would favor Cæsarean section after twenty-four hours of test labor, in preference to symphysiotomy, especially in view of the dangers from sepsis and hemorrhage in the latter.

Dr. M. McLean, of New York, advocated giving Nature more time, and he was not in favor of premature delivery. If Nature failed after a test labor of sufficient duration, he would advise Cæsarean section.

Dr. H. D. FRY, of Washington, was a convert to the advocacy of Cæsarean section, if a test labor showed that Nature had failed, and he believed this would be the advice of the obstetrician of the future. Version he regarded as an undesirable operation.

Dr. A. Lapthorn Smith said he had been unable to induce women who had borne dead children to submit to the induction of premature labor, and also to induce them to live upon a spare diet to minimize the development of the fœtus. To require that parents should be asked before doing an obstetric operation was often impracticable; the mother might be in agony or unconscious, and the father unable to judge as to the merits of the situation. This society should formulate the opinion that the elective Cæsarean section under proper conditions had no death rate. He believed it was much superior to accouchement forcé. Even in infected cases in which the Cæsarean section was performed the mothers could usually be saved if they were placed in the Fowler position with a large drainage tube in the uterus.

The Development of the Technique of the Gynæcological Operations.—Dr. A. MARTIN, of Berlin, Germany, reviewed the progress of the art during the past fifty years. The basis of the increasing value of gynæcological operations consisted in the more perfect knowledge of normal and pathological anatomy and of diagnosis. As to the vaginal and abdominal routes of attack, each method had its defenders. Much difficulty would arise from either method in the presence of adhesions. These must always be treated cautiously and intelligently, lest great injury be done to surrounding structures. The use of oil and other substances in the peritoneal cavity for the prevention of adhesions was not advisable. As to drainage, the method which used the vagina if possible was the most efficacious. Vaginal operations were preferable when the question of shock was of major importance. As to anæsthesia, it should always be as brief as possible. The vaginal route was valuable, but should not be used exclusively; it was not usually the best route to overcome dense adhesions, but it had the decided advantage that it could be abandoned if necessary, and an operation finished through an abdominal incision. The vaginal route was valuable in the treatment of displacements of the uterus, including prolapsus and its complica-tions, but it must not be forgotten that in many of the cases of displacement no operation was necessary. The vaginal route was also useful in the treatment of acute inflammations of the pelvic organs, and such treatment would often have a favorable bearing upon the question of subsequent pregnancy. In tubal gestation the abdominal route was preferable, especially after the third month; previous to that time the vaginal route could be used, especially if the tissues involved were encapsulated. Hæmorrhage in the pelvis should be treated by whichever method one could use to best advantage. In the treatment of cancer of the cervix the vaginal method was advocated, a wide dissection being made after Sehauta's plan. The abdominal route

gave the greater advantage in the inspection and treatment of the appendix, but disease of that organ was far less common in Europe than it seemed to

be in America.

Abdominal and Vaginal Cœliotomy for Gynæcological Operations; their Indications and Technics.-Dr. F. PFANNENSTIEL, of Kiel, Germany, stated that either method was available for the majority of gynæcological operations. That one should be preferred which in the judgment of the surgeon would give the best chances for life and health to the patient, primarily and secondarily. In all intraperitoneal diseases, the abdominal route offered the best opportunity for either radical or conservative work. Thus, in aseptic cases, this route would ordinarily be chosen for tumors, extrauterine gestation, chronic inflammations, malformations, etc. In septic cases in which the infectious material could be completely removed, the vaginal route was preferable, unless it was desirable that the entire operative field should be exposed to view. Disease of the appendix and cancer, except in very early invasion of the cervix, should be treated by the abdominal route. The vaginal route was also preferable for conditions of descensus and prolapse and for movable retrouterine displacements, colporrhaphy being a portion of the operative procedure. Either the anterior or posterior vaginal incision, or both, might be used, as occasion required. For the abdominal incision the method first suggested by the author, namely, the transverse incision, had been eminently satisfactory

D. C. P. Noble, of Philadelphia, in discussing the previous papers, stated that with suppurating ovarian tumors he preferred to operate radically by the abdominal incision primarily, rather than to evacuate and drain by the vagina, and subsequently remove the cyst. He agreed with Pfannenstiel in the eligibility of the vaginal route for myomectomy, if the myoma was smaller than a feetal head. He approved of the Pfannenstiel incision, and thought the recti muscles with that method would act as an effi-

cient support to the wound.

Dr. C. CLEVELAND, of New York, had found the Pfannenstiel incision useful in many cases, and thought it enabled one to get at the pelvic organs more readily than by the vertical incision. It also enabled one to protect the intestine sufficiently and to get at the appendix, which he always removed if it was abnormal in the slightest degree. The Pfannenstiel incision was especially useful with fat women, and often enabled one to obviate infection at the lower depression of the abdominal wall. In his technique he made use of the peritoneal suture and overlapped the fascia.

Dr. I. S. Stone, of Washington, believed that many of the problems in abdominal surgery could be worked out only by means of the abdominal incision, especially in cases in which any portion of the digestive tract was involved. In the tuberculous cases, which were extremely important, it was very difficult to do effectual work through the vagina. The Pfannenstiel incision had appealed to him in

many cases of abdominal disease.

Dr. J. R. Goffe, of New York, found it very interesting to hear the views of the two distinguished visitors, after their many years of experience. He admitted that he had reached the conclusion that

the scope of the vaginal route was not so great as he had long supposed. It was certainly to be preferred for the treatment of pelvic abscess and also hæmatocele, when infected. In fibroid tumors it was available unless the tumor was larger than a fœtal head. It had no advantage over the abdominal incision, unless the diseased organs were the more readily attacked by the vaginal route. He had found it a satisfactory avenue, not only for the plastic work of the vagina, but for the chronic inflammatory diseases of the pelvic organs, complicated with displacements. He preferred the anterior to the posterior vaginal incision, and the opening could be made as large as the vulva. The conservative work upon the pelvic organs could be done by this route, the tubes being spared when necessary. Drainage with gauze in such operations was effective.

Dr. H. J. Boldt, of New York, stated that he seldom operated upon the Falloppian tubes when in the acute stage of inflammation, but if it terminated in abscess pointing in the pelvis, he incised them through the vagina. In seventy-five per cent. of the cases of pelvic disease the appendix was involved, and it could best be reached through the abdomen. He made use of vaginal operations less frequently than formerly. If the round ligaments required shortening, he preferred Alexander's

operation.

Dr. R. L. Dickinson, of Brooklyn, had found that by using the Pfannenstiel incision with fat women, suppuration was not likely to occur. As to the vaginal or abdominal route, it was largely a question of personal skill and preference. It was quite possible to remove small ovarian and parovarian cysts by the vagina. In cases with adhesions, the abdominal route was preferable.

Dr. S. C. Gordon, of Portland. Me., advocated the drainage of tubes which were in an acute stage of inflammation by the vagina, and this was about all the use he had for the vaginal route. He adhered to the vertical median abdominal incision, and for closing the wound he still had faith in interrupted sutures of worm gut, closing the fascia with catgut. He was too old to go back to the

vaginal incision.

Dr. H. A. Kelly, of Baltimore, still persisted in the abdominal method, notwithstanding the excellent vaginal work which had been done by others. The vaginal route was proper enough for the injuries to the pelvic floor and the minor cases of pelvic disease. For the severe inflammatory diseases of the pelvis he preferred the abdominal way of attack, especially in the cases of large fibroid tumor and disease of the appendix. It also gave one a good opportunity to examine the gallbladder. The Pfannenstiel incision was useful, as already stated, for fat women.

Dr. C. C. FREDERICK, of Buffalo, thought there was a distinct field for each variety of incisions. He agreed with those who treated acute pelvic inflammation by the vaginal incision and drainage, but he never used this route for chronic pelvic disease. When ovaries were diseased only in part, he removed only the diseased portion. In the case of small fibromata or small ovarian cysts he operated through the anterior vaginal fornix.

(To be concluded.)

Book Antices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

An Index of Treatment. By Various Writers. Edited by ROBERT HUTCHISON, M. D., F. R. C. P., Physician to the ROBERT HUCHSON, M. D., F. K. C. F., Filystella to the London Hospital and Assistant Physician to the Hospital for Sick Children, and H. STANSFIELD COLLER, F. R. C. S., Surgeon to St. Mary's Hospital, etc. Revised to Conform with American Usage by WARREN COLEMAN, Conform with American Usage by Warren Coleman, M. D., Professor of Clinical Medicine and Instructor in Therapeutics in Cornell University Medical College, etc. New York: William Wood & Co., 1908. Pp. xv-888.

This is a practical presentation of therapeutics, partly medical and partly surgical. For the most part the headings are the names of morbid conditions, though a few of them are those of remedial measures, all arranged alphabetically, with a liberal system of cross references. Some of the articles are wholly therapeutical, but in many of them considerable space is taken up by matter more or less irrelevant to treatment. It is probably on this account that it was thought necessary to resort to the extensive use of very small type to prevent the volume from becoming unwieldy. The result is that it is not easy to read; however, it is not meant for continuous reading, but rather for reference. Another device for saving space is the printing of prescriptions in two columns. Had the page been made double columned, the book would, we think, have gained in appearance.

The contributors are seventy-two in number, and necessarily the articles vary greatly in value. Many of them will be found decidedly helpful by the general practitioner, and it is always well to avail ourselves of light from as many sources as possible. Among the best of the articles, in our opinion, are those on nephritis, by Dr. J. Rose Bradford and Dr. Samuel West. Some diseases appear to have been omitted, such as acidosis, kraurosis vulvæ, and amœbic dysentery. We do not find symmetrical gangrene entered under its own head, and the student who is not familiar with the literature of the subject may imbibe from the book the notion that Raynaud's disease is but another name for chilblains.

Some remedial measures more or less esteemed seem to have escaped notice. For example, we find no mention of yeast in the article on boils or in the one on leucorrhœa; high frequency currents appear to have eluded the author of the article on electrotherapeutics; if there is any mention of radium, the x rays, and the Finsen light treatment, we have failed to find it; the salts of cotarnine are not referred to in connection with uterine hæmorrhage; alcohol does not figure in the treatment of carbolic acid poisoning; and cerium oxalate and ipecac find no place in the article on the vomiting of pregnancy. This, we must say, is a weighty list of omissions.

At least one subject is considered more than once. Mammary abscess is treated of on page 4 and again on page 484, and in addition there is an article on mastitis. In the article on pruritus vulvæ we find this rather astonishing statement: "Pediculi pubis may be the cause of pruritus, but probably only

when their presence is accidental rather than habitual." We congratulate the editors on their reference of "enteric fever" to typhoid fever. The term enteric fever has never found favor in this country, and our opinion is that it does not deserve recognition.

We have noted some faults of expression, such as these: "At right angles to the anus" (page 3), "this" [Lister's method of anæsthetizing with chloroform] "consists in drawing the corner of a towel through a safety pin till a mask is formed reaching from the chin to the root of the nose," and "although tetanus is one of the few organisms," etc. We find the following inconsistent statements in the article on blackwater fever: "Ouinine is useless, and in some instances has caused the attack. If the parasites of malaria continue to be present during the attack, quinine is necessary." As a rule, the prescriptions are printed with unusual accuracy. On page 7, however, we find the following directions: "Fiat Chartula No. j. Every four hours." How can one and the same powder be taken every four hours?

Dr. Coleman's appendix is exceedingly useful. It contains "brief descriptions of preparations in common use in Great Britain, but comparatively unknown in America." Many of these preparations are proprietary.

Life Insurance and General Practice. By E. M. Brock Bank, M. D. (Vict.), F. R. C. S., Honorary Assistant Physician, Royal Infirmary, Manchester, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. xiv-288.

Intended primarily for the use of life insurance examiners, this recent addition to the excellent series of Oxford medical publications cannot fail to interest a much larger circle of medical readers. It really contains a well written exposition of all the practical points in physical diagnosis, and in the section on impaired lives considers in an adequate manner the important subjects in relation to life insurance of tuberculous disease, cancer, alcoholism, syphilis, and other organic diseases. There are brief but interesting chapters on deformities and abnormities, sea and war risks, and the special dangers incident to life in the tropics and dangerous climates. The physician will find in this modern work of Dr. Brockbank's many familiar facts discussed from a novel view point.

Miscellany.

How to Enter the Army Medical Corps.—The following is the substance of recent circulars of information:

The Medical Corps now consists of a surgeon general with the rank of brigadier general, fourteen colonels, twenty-four lieutenant colonels, one hundred and five majors, and three hundred captains or first lieutenants with rank, pay, and allowances of officers of corresponding grades in the cavalry.

Vacancies in the Medical Corps are filled by appointment to the junior grade (first lieutenant). After three years' service lieutenants, upon passing an examination to determine their fitness, are promoted to the grade of equite in

moted to the grade of captain.

Promotion to the grades of major, lieutenant colonel, and colonel is by seniority, but there is an examination for that of major and another for that of lieutenant colonel. Advancement to the grade of colonel takes place without further examination. The surgeon general is selected by the President from among the officers of the corps.

To each rank is attached a fixed annual salary, which is received in monthly payments, and this is increased by ten per cent. for each period of five vears' service until a maximum of forty per cent. is reached. A first lieutenant receives \$2,000 per annum, or \$166.66 monthly. At the end of three years he is promoted to the rank of captain and receives \$2,400 a year. In two years more he receives an increase of ten per cent. for five years' service, making \$2,640, or \$220 a month. Aften ten years' service the pay would be \$2,880 annually, or \$240 a month. The pay attached to the rank of major is \$3,000 a year, which, with ten per cent. added for each five years' service, becomes \$3,600 after ten years' service, \$3,000 aften fifteen years' service, and \$4,000 after twenty years. The monthly pay of lieutenant colonel, colonel, and brigadier general is \$375, \$416.66, and \$500, respectively. Officers, in addition to their pay proper, are furnished with a liberal allowance of quarters according to rank, either in kind or, where no suitable government building is available, by commutation; fuel and light therefor are also provided. When traveling on duty an officer receives mileage for the distance traveled, including the travel performed in joining his first station after appointment as first lieutenant; the amount allowed is usually sufficient to cover all expenses of the journey. On a change of station he is entitled to transportation for professional books and papers and a reasonable amount of baggage at government expense. Mounted officers, including all officers of the Medical Corps, are provided with forage, stabling, and transportation for horses owned and actually kept by them, not exceeding two for all ranks below that of brigadier. Horses and horse equipments are furnished by the government for all mounted officers below the grade of major. Groceries and other articles may be purchased from the commissary at about wholesale cost price. Instruments and appliances are liberally supplied for

the use of medical officers in the performance of their duties. Well selected professional libraries are supplied to each hospital, and standard modern publications on medical and surgical subjects are added from time to time; current issues of a number of representative medical journals are also furnished for the use of medical officers.

Leave of absence on full pay may be allowed at the discretion of the proper authority at the rate of one month a year, and this when not taken may accumulate to a maximum of four months, which at the end of four years is then available as one continuous leave. Beyond this an officer may still be absent with permission on half pay. Absence from duty on account of sickness involves no loss of pay.

Medical officers are entitled to the privilege of retirement after forty years' service or at any time for disability incurred in the line of duty. On attaining the age of sixty-four they are placed upon the retired list by virtue of law. Retired officers receive three fourths of the pay of their grade (salary

and increase) at the time of retirement.

When medical officers with the rank of captain approach the period of their examination for promotion to a majority, they are usually assigned to duty as attending surgeons at or near the principal medical centres of the United States, to enable them to become familiar with the practice of the leading physicians and surgeons of this country, and to attend medical lectures, meetings of medical societies, etc. These assignments are made for one year only, in order that as many medical officers as possible may be enabled to avail themselves of the advantages thereby afforded. At the end of this tour of duty they are required to make a detailed report to the surgeon general, showing how much of their time has been occupied by their official duties and to what extent they have availed themselves of the advantages offered for professional advance-

Appointments to the Medical Corps of the army are made by the President after the applicant has passed a successful examination before the Army Medical Examining Board and has been recommended by the surgeon general. Due notice of the meeting of the board is published in the medical journals.

Permission to appear before the board is obtained by letter to the adjutant general of the army, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident, and inclosing certificates, based on personal acquaintance, from at least two reputable persons as to his citizenship, character, and habits.

An applicant for appointment in the Medical Corps of the army must be between twenty-two and thirty years of age, a citizen of the United States, and a graduate of a reputable medical school legally authorized to confer the degree of doctor of medicine, in evidence of which his diploma will be submitted to the board at the time of his preliminary

examination.

Hospital training and practical experience in the practice of medicine, surgery, and obstetrics are essential, and an applicant will be expected to present evidence that he has had at least one year's hospital experience or the equivalent of this in practice.

The examination will consist of two parts—a preliminary examination and a final, or qualifying, examination, as hereinafter described, with a course of instruction at the Army Medical School intervening.

Preliminary examination will be required as follows:—

(a) Physical. The physical examination must be thorough. Candidates who fall below 65 inches in height will be rejected. Each candidate is also required to certify that he labors under no physical infirmity or disability which can interfere with the efficient discharge of any duty which may be required. Errors of refraction, if vision is not below 20/40 in either eye, are not causes for rejection, provided they are not accompanied by ocular disease and are entirely corrected by appropriate glasses.

(b) Written examination on the following subjects: Mathematics (arithmetic, algebra and plane geometry), geography, history (especially of the United States), general literature, Latin grammar, and the reading of easy Latin prose. English grammar, orthography, and composition will be determined from the applicant's examination papers.

This examination may be omitted in the case of applicants holding diplomas or certificates from reputable literary or scientific colleges, normal schools, or high schools, or of graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School.

factory to the faculty of the Army Medical School.

(c) Written examination in the following subjets: Anatomy, physiology and histology, chemistry and physics, materia medica and therapeutics, surgery, practice of medicine, obstetrics, and gynæcology.

The preliminary examinations will be conducted by boards of medical officers at the larger military stations in the United States, the questions in the several subjects being sent from this office. Formal invitations will be extended to eligible applicants to appear at the most convenient points at which boards are convened and a date fixed for such appearance, which will be uniform throughout the country. No allowances can be made for the expenses of applicants undergoing preliminary examinations.

Applicants who attain a general average of not less than 80 per cent, in the preliminary examinations will be appointed to the Medical Reserve Corps with the rank of first lieutenant and ordered to the Army Medical School, Washington, D. C., for instruction as candidates for admission to the Medical Corps of the army. If, however, a greater number of applicants attain the required average than can be accommodated at the school, the requisite number will be selected according to relative standing in the examination. An applicant thus selected will, before entering the school, be required to make an agreement to accept a commission in the Medical Corps if found qualified in the final examination, and that he will serve at least five years thereafter, unless sooner discharged. Candidates undergoing instruction at the Army Medical

School will receive the pay and allowances of first lieutenants, including travel pay from their homes to Washington.

An applicant failing in one preliminary examination may be allowed another after the expiration of one year, but not a third; withdrawal from examination during its progress, except because of sickness, will be deemed a failure.

The course of instruction at the Army Medical School will be of eight months' duration, commencing on the first of October next succeeding the pre-liminary examination; it will consist of lectures and practical work in such subjects as are peculiarly appropriate to the duties which a medical officer of the army is ordinarily called upon to perform. During this course of instruction the candidates will be held under military discipline, and character, habits, and general deportment closely observed; if for any reason a candidate should be deemed undesirable, he may at any time, on the reommendation of the surgeon general, be honorably discharged by the President.

The final examination shall comprise the subjects taught in the school, namely: Duties of medical officers, Medical Department administration and customs of the service, military hygiene, clinical microscopy and bacteriology, military surgery, military and tropical medicine, sanitary chemistry, Hospital Corps drill, operative surgery, ophthalmology and optometry, and x ray work. It will be preceded by a thorough physical examination.

Candidates who, in their final examination, obtain a general average of 80 per cent. and upward shall be given certificates of graduation at the school, and those whose aptitude, as determined by the faculty, is deemed satisfactory and who, in addition to their final examination, pass a successful clinical examination, will be selected for commission in the Medical Corps. Candidates professing a knowledge of ancient or modern languages, higher mathematics, or scientific branches, other than medical, may be given a special examination therein.

The relative standing of the candidates thus selected for commission will be determined by the total number of points obtained in the professional subjects of the preliminary examination as well as in the final, clinical, and special examinations, and for antitude

Candidates who fail to receive commissions because of lack of vacancies in the Medical Corps at the time of graduation may receive them in the order of their standing as vacancies occur before the graduation of the next class. The remaining qualified candidates, if any, will be preferred for selection for volunteer commissions and for assignment on active duty in the Medical Reserve Corps.

Any candidate who, at his final examination, fails to qualify mentally shall not be entitled to a reexamination. Any candidate who qualifies mentally, but fails physically, shall, upon the recommendation of the surgeon general of the army, be given an opportunity to be reexamined physically with the next class, and if then found qualified may be commissioned without further mental examination, his standing in the class being determined by the aggregate of the marks obtained in the examinations already passed by him.

The act approved April 23, 1908, gives an increase in the corps of six colonels, twelve lieutenant colonels, forty-five majors, and sixty captains or first lieutenants. The increase in the higher grades insures promotion at a reasonable rate all through an officer's military career. The first advancement to the grade of captain takes place after three years instead of five, as heretofore, and this rapid promotion, together with the liberal pay now given all officers of the army, offers such manifest advantages to young physicians that the very best and most representative graduates of our medical schools should be attracted thereby. As accepted candidates for the Medical Corps are appointed first lieutenants of the Medical Reserve Corps during their service and instruction at the Army Medical School, there is no delay in receiving the pay of lieutenant, and no final loss of relative rank in the corps to those who successfully pass through the school, as no appointments are made to the Medical Corps except from the successive graduating classes from the school.

The period of instruction at the school, although an anxious time for the candidate, is looked back upon by the graduates as a most pleasant and profitable part of their service. The time of all students is fully occupied, but those who work steadily and faithfully and are well grounded in medicine need

not fear failure at the end.

The large number of vacancies created by recent legislation makes it certain that all successful candidates will be recommended for commission for several years to come.

It will be to the advantage of the candidate to pass the required examination and secure a com-

mission at as early a date as possible.

Applications for permission to appear for examination, prepared in accordance with requirements before mentioned, should be sent to the adjutant general of the army, and when completed will be filed until the next succeeding preliminary examination shall have been decided upon, when formal invitations to appear before a board will be issued. Applicants are advised to file the necessary papers as early as practicable, in order that the places of examination may be arranged most conveniently to applicants, due regard being had to the interests and necessities of the service.

Official Rews.

Public Health and Marine Hospital Service:

Official list of changes in the stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending June 24, 1908:

Berry, T. D., Passed Assistant Surgeon. Placed on waiting orders, from June 1, 1008.

CLARK, E. S., Assistant Surgeon. Granted leave of absence for ten days, from June 11, 1908.

GARDNER, C. H., Passed Assistant Surgeon. Relieved from duty at San Francisco, Cal., and directed to proceed to Wilmington, N. C., assuming command of the service

Wilmington, N. C., assuming comments at that port.

LAVINDER, C. H., Passed Assistant Surgeon. Relieved from duty at Wilmington, N. C., and directed to proceed to Stapleton, N. Y., reporting to the medical officer in command, for duty and assignment to quarters.

MANNING, H. M., Assistant Surgeon. Directed to report to the chairman of a board of examiners at the bureau, Washington, D. C., July 6, 1908, for the purpose of determining his fitness for promotion to the grade of termining his fitness for promotion to the grade of passed assistant surgeon; granted leave of absence for

Seven days.

Mason, M. R., Pharmacist. Granted leave of absence for twenty-eight days, from July 15, 1908.

RUSH, J. O., Acting Assistant Surgeon. Granted leave of absence for fourteen days, from July 1, 1908.

STODDARD, C. S., Acting Assistant Surgeon. Granted leave of absence for thirty days, from June 27, 1908.

WATERS, M. H., Pharmacist. Granted leave of absence for thirty days from July 1, 1908.

for thirty days, from July 1, 1908.

White, M. J., Passed Assistant Surgeon. Granted extension of leave of absence for fifteen days, from July I, 1908.

WILLIAMS, L. L., Surgeon. Granted leave of absence for one month, from July 15, 1908.

Board Convened.

A board of medical officers was convened to meet at Seattle, Wash., for the purpose of examining alien immigrants. Detail for the board: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin; Acting Assistant Surgeon F. R. Underwood, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending June 27, 1908:

GRISSINGER, J. W., Captain. Leave of absence extended to

July 24, 1908.
GRUBB, R. B. Captain. Left Fort McIntosh, Tex., for Leon Springs, Tex.
HARRIS, H. S. T., Major. Leave of absence further ex-

tended one month.

tended one month.

HEYSINGER, J. D., Captain. Ordered from Key West Barracks, Fla., to Chickamauga Park, Ga., for duty.

LA GARDE, L. A., Lieutenant Colonel. Assigned to duty as attending surgeon, Denver, Col., in addition to duties as chief surgeon, Department Colorado.

LEWIS, W. F., Major. Left Fort Sill, Okla., with troops for Leon Springs, Tex.

Morris, S. J., Captain. Granted leave of absence for two months, to take effect about August 15th.

REYNOLDS, C. R., Captain. Ordered to duty as commanding officer of Company C, H. C., Army General Hospital, Washington Barracks, D. C.

WICKLINE, W. A., Captain. Left Army General Hospital, San Francisco, Cal., with one half of Company B, H. C., for duty at Leon Springs, Tex.

H. C., for duty at Leon Springs, Tex.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the sock and a June 27, 1008.

ALLEN, D. G., Assistant Surgeon. Ordered to the naval medical school, Washington, D. C. BLACKWELL, E. M., Passed Assistant Surgeon. Ordered to the Naval Academy, Annapolis, Md. Bogan, F. M., Passed Assistant Surgeon. Detached from the naval recruiting station, Minneapolis, Minn., and or-

dered to the Wisconsin.

Brown, H. L., Passed Assistant Surgeon. Detached from the naval station, Cavite, P. I., and ordered to the

CLARK, G. F., Assistant Surgeon. Ordered to the

ENGLAND, S., Pharmacist, retired. Detached from the navy yard, Mare Island, Cal.
KERR, W. M., Assistant Surgeon. Ordered to the Naval Hospital, New York.
LANDO, M. E., Assistant Surgeon. Ordered to the naval

recruiting station, Minneapolis, Minn.

McClurg, W. A., Medical Director. To be placed on the retired list, September 1, 1908, upon his own application, with completion of thirty years' service, in accordance with a provision of the naval appropriation

act of May 13, 1908. RANDALL, J. A., Passed Assistant Surgeon. Detached from

the Denver and ordered to the Rainbow.
RODMAN, S. S., Passed Assistant Surgeon. Detached from the Rainbow and ordered home.

the Rambow and ordered home.

SMITH, C. W., Assistant Surgeon. Ordered to the Naval Hospital, Portsmouth, N. H., and to additional duty at the naval prison at that yard.

STALNAKER, P. R., Assistant Surgeon. Ordered home and granted leave for two months.

TAYLOR, J. L., Assistant Surgeon. Ordered to the Naval Hospital, New Fort Lyon, Col.

TRIBLE: G. B., Assistant Surgeon. Detached from the Naval Hospital Nava Land Col. and ordered to the

Naval Hospital, Mare Island, Cal., and ordered to the

WHELER, W. M., Surgeon. (Orders issued by Commander, Third Squadron, Pacific Fleet.) Detached from the naval station, Cavite, P. I., and ordered home.

Births, Marriages, and Deaths.

Born.

Purnell.—In Fort Mackenzie, Wyoming, on Saturday, June 20th, to Dr. Harry S. Purnell, United States Army, and Mrs. Purnell, a son.

Married.

BARROWS—ROBERTSON.—In Denver, Colorado, on Wednesday, June 17th, Dr. Frank Barrows and Dr. Bessie B. Robertson.

CHILES—HOWARD.—In Pulaski, Virginia, on Wednesday, June 17th, Dr. Joseph Haskell ('hiles and Miss Ida Miller

FREEMAN-MARKS-In Louisville, Kentucky, on Wednesday, June 17th, Dr. John A. Freeman, of Beard, and Miss Edna Marks.

HAGEN—CRANDALL.—In Troy, New York, on Thursday, June 18th, Dr. Joseph J. Hagen and Miss Leona Crandall. MULHOLLAND—DODIN.—In New York, on Tuesday, June 16th, Dr. Joseph A. Mulholland and Miss Josephine Dodin. Norris—Horsey.—In Crisfield, Maryland, on Wedness Level 18th, Dr. Description

day, June 24th, Dr. Rastus Ransom Norris, of Baltimore, and Miss Lillian Horsey.

ROSENKRANZ-HAYMES.-In Philadelphia, on Wednesday, June 17th, Dr. Otto H. G. Rosenkranz and Miss Inez

SHOEMAKER—GILMAN.—In New York, on Thursday, June 4th, Dr. Harlan Shoemaker, of Philadelphia, and Miss

Grace Clyde Gilman, of Redlands, California, Strong—McMillan,—In New York, on Wednesday, June 17th, Dr. Cyrus Strong and Mrs. Helen Frisbie Mc-

VAN KIRK—JORDAN.—In New York on Wednesday, June 24th, Dr. Harry Hill Van Kirk, United States Army, and Miss Henrietta Clark Jordan.

Weber—Baker.—In Hyattsville, Maryland, on Saturday, June 20th, Dr. Frederick Clarence Weber, of Columbus, Ohio, and Miss Alice Louise Baker.

Donohue.—In Washington, District of Columbia, on Wednesday, June 24th. Dr. Florence Donohue.

Martin.—In Des Moines, Iowa, on Thursday, May 28th,

MARTIN.—In Des Moines, Jowa, on Thursday, May 2011, Dr. L. B. Martin, aged seventy-six years.

MILLERICK.—In Stoncham, Massachusetts, on Thursday, June 18th, Dr. Daniel E. Millerick, aged fifty-two years.

NEVILLE.—In Brooklyn, New York, on Monday, June 22d, Dr. Michael J. Neville, aged forty-nine years.

PRESTON.—In Baltimore, on Wednesday, June 17th, Dr.

George J. Preston, aged fifty years.
PURDY.—In Brooklyn, on Saturday, June 20th, Dr. James

Purdy, aged seventy-six years. REILLY.—In West Plains, Missouri, on June 17th, Dr. REILLY.

J. F. Reilly.

VAN DE VEER.—In Louisville, Kentucky, on Thursday,
June 18th, Dr. John G. Van De Veer.

Warrs.—In New York, on Monday, June 8th, Dr. Robert

Watts, Jr., aged forty-two years.

A REVIEW OF THE COURSE IN OBSTETRICS IN THE UNIVERSITY OF PENNSYLVANIA.

Being the Final Lecture to the Graduating Class.

By Barton Cooke Hirst, M. D., Philadelphia.

It is difficult to review in an hour what we have learned in two years, but I can sketch an outline that will refresh your memory. We began with the diagnosis of pregnancy; its difficulties and the liability to serious error without a systematic, methodical examination of the patient. An ovarian cyst and a fibroid tumor were operated on before the class, the opportunity being taken to illustrate the differential diagnosis between the commonest pathological abdominal tumors and by far the commonest physiological tumor, pregnancy.

Next we took up the management of normal

pregnancy.

In a course designed to be as systematic as our clinical material permits, we next presented examples of the commonest complications of pregnancy, especially the two toxemias and the premature interruption of pregnancy. We learned that there are two toxemias of pregnancy, that of the first half and that of the second half, the former characterized by vomiting and ptyalism; a strong neurotic element; low blood pressure; possibly degeneration of the liver; but no functional or organic disease of the kidneys; and only such anomalies in the urine as can be found in any case of starvation and excessive vomiting-namely, a disarrangement of nitrogen partition and concentration. Death, if the disease is fatal, comes only after days of progressive exhaustion. The toxemia of the latter half is characterized by high blood pressure; both functional and organic disease of the kidney; albumin, casts and blood in the urine; secondary degeneration of the liver and all the viscera due to multiple hæmorrhages; convulsions; coma; cedema of the brain and lungs, with a fatal issue or recovery as a rule within forty-eight hours,-obviously two distinct diseases. We indulged in some speculation-it can be nothing more at presentabout the ætiology of these two diseases, believing that the first was a syncytial poisoning of the maternal organism, and that the second was due to toxines from feetal metabolism. Numerous demonstrations were given of the treatment of the toxæmia of late pregnancy by eliminative and sedative remedies, and measures to reduce the blood pressure. One demonstration was given to the class of the ultimate treatment of toxemia of early pregnancy—the induction of abortion by dilating the cervix, crushing the ovum, removing a portion of it, packing the uterus, and evactuating it on the following day.

The treatment of incomplete abortion by the instrumental evacuation of the uterus was illustrated several times, and you were warned of the danger of perforating the uterus in this minor and common operation. After exhibiting some examples of the rarer complications of pregnancy we passed to the

management of normal labor.

Next came in natural order the care of the puerperium. As an essential item in the management of a puerpera we insisted that three examinations should be made: One in the first week to detect lacerations of the birth canal; another at the end of three weeks to learn the position of the uterus; and the third at the end of six weeks-the conclusion of puerperal convalescence-to determine the condition of the vulvar orifice, the pelvic floor, and the anterior vaginal wall; lacerations, erosions and eversions of the cervix; the involution of the uterus; its position; the condition of the appendages and broad ligaments; the abdominal walls, and the appendix; the position of the kidneys; and the condition of the coccyx. Numerous cases of complicated and obstructed labors have been exhibited to this class; post partum hæmorrhage requiring an intrauterine pack; placenta prævia requiring an enormous vaginal tampon temporarily and, when everything is ready for it, podalic version, or possibly, in exceptionally favorable cases of cephalic presentations, the application of forceps. Premature detachment of the placenta, concealed hæmorrhage, and the evacuation of the uterus demanded by it, and abdominal sections for cases of ruptured uterus.

You have been shown the commonest types of contracted pelves, the simple flat, the rachitic, and the justo minor; and the methods of diagnosticating them by pelvimetry. Also the methods of comparative ante partum feetometry; that is, the estimation of the relative size of feetal head and maternal pelvis

before birth.

Every kind of obstetrical operation required for obstructed labor has, I think, been witnessed by this class. Numerous inductions of labor by instrumental dilatation, bougies and bags: many forceps operations; version; pubiotomy. Cæsarean section; craniotomy; section of the clavicle, decapitation; have all been exhibited. You have had the opportunity to observe the operative and aseptic tech-

nique, to learn the indications for the operations, the precautions necessary, and in some instances the difficulties occasionally encountered.

We have been able to illustrate the various infections of the puerpera, many examples of which

are referred to the hospital.

You have seen numerous cases of mastitis, and have become familiar with the best operative technique for mammary abscess; namely, numerous small incisions which do not subsequently disfigure the breast and extensive counter drainage; the new treatment by Bier's vacuum apparatus has been given a trial, but the results have not been so good as are obtained by our own method of treatment. In each instance in which the local hyperæmia by vacuum was tried, we were obliged ultimately to resort to multiple incisions and counter drainage.

The infection of the genital tract has engaged our attention off and on during both years. The differential diagnosis between the fever of streptococcic, staphylococcic, gonococcic, or other wound infection and the accidental febrile complications of the puerperium has been studied in many cases. have learned the value of the bacteriological examination of the blood and of the lochia, the leucocyte count, the character of the fever, and of the pulse; the importance of the physical examination by abdominal palpation, combined vaginal and abdominal examination, and the inspection of the genital tract, in the diagnosis of puerperal sepsis. You have also seen the gratifying success of the treatment of puerperal infection in a larger proportion of cases than would seem possible in view of the dangerous character of the disease, by stimulation and support; by injection of salt solution to stimulate elimination; by leucocytoccic action of protonuclein; by surgical intervention when indicated; possibly by streptococcic vaccines; certainly in some cases by antistreptococcic serum, and by the instrumental evacuation and the disinfection of the uterine cavity. Let me dwell a moment on the There is an easily underlast statement. stood prejudice in the profession against what is called curettage of the puerperal uterus for infection, due to the fact that the ill informed and unskillful physician has too often perforated the soft wall of the uterus after childbirth or has broken through the barrier of granulation cells under the infected endometrium with his curette, thus converting a localized into a general infection. But we have learned that curettage is an incorrect term to use in describing the instrumental exploration of the uterine cavity in cases of infection. The curette, if used at all, is a dull curette employed with the utmost gentleness; as a matter of fact, the curette forceps of Emmett is the better instrument, and one that can do no harm if skillfully employed. On the contrary, the exploration of the uterine cavity, the removal of necrotic decidua, the irrigation of the uterus with alcohol, water, and tincture of iodine or with formalin, glycerin, and water is often essential to success.

Finally in concluding our review of the conditions demonstrated during the third year, I must remind you of cases of puerperal insanity, unusual sequelæ of eclampsia, such as gangrene of the lungs; an extreme case of chorea, in pregnancy, end-

ing fatally; pyelitis gravidarum with demonstrations of cystoscopy and catherization of the ureters; so called inspiration pneumonia in the new born; appendicitis in pregnancy and puerperal hæmorrhages, all of which have been shown you. The last named, you recollect, usually indicates the retention of secundines in the uterus, but there are other causes, among them a possibility of chorionepithelioma, which must not be forgotten.

I have been obliged to trust to your collateral reading for the information you should possess about the mechanism of labor, including anomalies of presentation and position with their treatment, which cannot be demonstrated clinically, but which must be understood to intelligently supervise normal labor or to successfully perform the obstetrical operations. In fact if you have not covered the whole subject of obstetrics at least once in some textbook my course is a comparative failure.

In the studies of the fourth year, I have endeavored to fulfill a part of my duty to you which is too often neglected in the obstetrical depart-

ments of American medical schools.

Until the present generation the obstetrical departments of the best medical schools of this country were ridiculously ill equipped. There was not a bed nor a patient; the incumbent of the chair had no hospital training or facilities, so that he was incompetent to teach a most important part of his subject. It is universally acknowledged that obstetrics includes not only the act of delivery, but all the consequences and complications of the child bearing act at all periods, most of which demand surgical treatment. This, I say, is generally admitted; and in the great medical schools of Europe, well equipped with adequate hospital facilities, the professor of obstetrics has taught his subject in its entirety. If you consider what this means you will see the reason why in all the best medical schools of Europe, that is to say, the medical schools of the most highly civilized portions of the world, the professor of obstetrics has necessarily been charged with the treatment of the diseases of women, for if you subtract the consequences and complications of the child bearing act from the diseases of women there is nothing left. Here, on the contrary, it was necessary for a time to create a special department covering this branch of obstetrics, because the incumbent of that chair had neither the training nor the facilities to do his whole duty by the subject. Recently this discreditable condition of affairs has been remedied. In the last few years it has been possible to raise this department in our medical school to a parity with similar departments in the best medical schools in the world, with the single exception that we have not yet accumulated a sufficient amount of clinical material, although the two thousand women a year under my control, available for clinical teaching, an imposing total for America, is respectable anywhere, and every year witnesses a gratifying increase.

Now, therefore, I am at last able to present my subject to you as it should be and is presented in the best medical centres. In justice to my subject, in justice to you, and in justice to myself I must do this. But in doing so I necessarily duplicate a certain amount of the teaching of my colleague, the

professor of gynæcology, just as the three professors of surgery and the three professors of medicine necessarily duplicate to a certain extent one another's teaching. This, however, is no disadvantage to you. On the contrary, if there should be differences of opinion and different methods it is distinctly to your advantage to hear and see them. It shows the same subject from different points of view. It develops the critical faculty in you which must be exercised during the whole of your professional life. Moreover, in this clinic you may see better illustrated than it can be elsewhere the immediate relationship between the child bearing process and the numerous ills peculiar to womankind dependent upon it. Most important of all, we are in a position here to demonstrate to you the preventive treatment of the vast majority of the diseases of women, and it is in this direction that all medical progress tends.

Let me now recapitulate what we have learned

this year.

You have had the course in obstetrical operations on the manikin; the independent clinical training in the South Eastern Dispensary service; the ward classes, and during the last half of the year, the clinics. In the ward classes and clinics, I have followed a plan which is the result of some experimentation and considerable reflection. The keynote of it is the restoration to the normal of the woman after childbirth and the best surgical treatment for the prevention of conditions which are quite unnecessarily invaliding a large proportion of our adult female population.

The commonest diseases of women are the results of lacerations of the birth canal. We have taught you—or, better, we have given you the opportunity to learn for yourselves—how to recognize the existence and the extent of any of them anywhere. Not by a cursory examination directly after child-birth, with the tissues swollen, bruised, distorted, and stretched so that no one could possibly make a correct diagnosis, but a few days after labor, with the patient arranged in the position necessary for any accurate gynaeological diagnosis, with a good

light and the aid of a speculum.

To any reasonable mind it is plain that this plan is better than the old one and must supersede it. You remember the logical order of this examination: The inspection of the vulva to detect injury of the junction of the bulbocavernosus and of the transversus perinei muscles, by the gaping of the vulvar orifice; the test of the integrity or injury of the levator and muscles, (1) by sinking the forefinger, inserted to the second joint, first in one posterior sulcus and then in the other; (2) by sweeping the forefinger from one descending ramus of the pubis, around the curve of the muscle, to the other ramus; (3) by putting both forefingers at once in the posterior sulci; and (4) by palpating the whole breadth of the muscle in each sulcus between the forefinger and the thumb, one externally on the labium, the other internally. If there is a complete tear, through the sphincter, it is usually recognized at a glance, with the patient in the dorsal gynæcological position. If there is any doubt about it the forefinger in the rectum and the thumb in the vagina determine the thickness of tissues between and the rupture of the ring of the sphincter muscle. You recollect the method of diagnosticating injuries of the anterior wall in its lower third by pressing the palmar surface of the forefinger upward and outward in the anterior sulci, where the muscle of the urogenital trigonum is often ruptured. You recall the surest way to recognize injuries, erosions, and eversions of the cervix, not by palpation, but by inspection, preferably through a bivalve speculum.

Next for the lessons we have learned in the surgical technique of the repair of injuries in each of these localities: In the sulci of the posterior wall the closest apposition of the edges of the torn levator ani muscle is secured by the double tier suture of chromicized gut; the bulbocavernosus and the transversus perinei muscles are rejoined by a deep insertion of a curved needle threaded with silk worm gut.

If for a special reason—prolapsus uteri—in a woman not expected to bear any more children, it is desired to narrow the vagina and build up a pelvic floor of unusual strength, the whole posterior third of the vaginal wall is denuded and the raw surfaces joined in the middle line—a procedure known as "Hegar's operation."

In the repair of a complete tear, if you bear in mind certain cardinal principles, you will have uniform success. Otherwise you must expect the fifty per cent. of failures to which even some specialists confess. Stretch the sphincter; denude so that the sphincter pits are exposed; dig a strong tenaculum to the bottom of each sphincter pit and bring the end of the muscle to the surface in plain sight; join the ends firmly with at least two unabsorbable sutures; keep the bowels fluid for three weeks after the operation and soft for three months.

In the repair of the anterior wall we have a more complicated problem, but a problem that is solved. We had first to learn what happened to the anterior vaginal wall in labor that weakened its support, and it took us an unconscionable time to find it out, but thanks to the anatomical investigations of Waldeyer and careful clinical observations by numbers of us practical workers, we know now that three distinct kinds of injury are inflicted upon the anterior vaginal wall and the subjacent tissues which support it, by the passage of the fœtal head through the birth canal: One is an elongation of the longitudinal ligaments, principally the uterovesical; the second is a lateral separation of the fascial plates under the vaginal wall, analogous to the separation of the recti muscles in the abdominal wall; and the third is a laceration of the muscle and fascia of the urogenital trigonum in the anterior vaginal sulci, the only support possessed by the lower third of the anterior vaginal wall. It is possible to repair a part of this damage in the early puerperium, by uniting the urogenital trigonum muscle, and possibly by bringing together the outer thicker portions of the fascial plates. If this should prove insufficient to prevent a cystocele, or if we see a patient in whom a cystocele has developed, because there has been no attempt to prevent it, we have recently perfected

an operative technique based on correct anatomical and clinical knowledge, which as surely and permanently cures a cystocele as Emmet's or Hegar's operations cure a rectocele; namely, the severance of the uterovesical ligament, the exposure and junction of the fascial plates, and the repair of the urogenital trigonum muscle. This procedure must replace the old oval and circular denudations with a puckering stitch—mere empirical devices, with a huge percentage of failures.

In the cervix we find only two injuries: An annuar detachment and longitudinal lacerations. The first is a spontaneous amputation and requires no further surgical treatment, unless it is incomplete, when it may be necessary to amputate a tab of cervical tissue left behind. The second, no matter how extensive or numerous, may be repaired by the appropriate plastic operation at any time after the fifth day of the puerperium. Before that time there is too much danger of infection of the endometrium.

The second in frequency among the pathological consequences of the child bearing process, the second in frequency among the diseases of women, is retrodisplacement of the uterus. Lacerations of the birth canal and backward displacements of the uterus constitute in point of numbers three fifths of all the diseases of women. We have learned the necessity of a careful pelvic examination at three weeks and again at six weeks after childbirth, to determine the position of the uterus. If a retroflexion or version is discovered, you recall, no doubt, the scheme of treatment advised; reposition and the knee chest posture twice a day until the sixth week; in the wealthy, leisure classes, if the displacement persists in spite of postural treatment, a pessary, Swedish exercises, and massage for eight weeks. If the displacement still persists, the choice between a pessary indefinitely and radical cure by operation, the physician naturally preferring and advising the latter course. In the poorer, working classes nothing but an operation need be considered. Of the numerous (more than fifty) operations for these displacements, my personal opinion is that there are only four worth attempting: The Alexander operation, as modified by Edebohls; ventrosuspension; Mayo's modification of the Gilliam operation; and the operation proposed independently and coincidently by Webster and Baldy. You have seen each of these operations in this clinic and have heard them described. You must decide which one of them appeals most to your reason. If my opinion of their relative merits is of any value to you, I unhesitatingly express a preference for shortening the round ligaments in the inguinal canals; but the displacement must be uncomplicated, which is not often the case. Ventrosuspension has been the most available operation in my practice, though it is unnatural and unanatomical, and I hope will be superseded by something better. The Gilliam and Mayo operations I am not so well pleased with after a trial of two or three years. Baldy's and Webster's operation looks promising, but I am only beginning to try it in corpore vili-that is, on my ward patients; I have confidence in the judgment of its authors. I like it as far as I have personal experience

with it, and Dr. Baldy, who has utilized it for four years, assures me the results are permanent.

Next in importance among the pathological sequelæ of childbirth, to lacerations of the birth canal and retrodisplacements of the uterus, is septic infection. We have already referred to this subject. It only remains to remind you of the indications for and the surgical technique of the operative treatment. If physical signs of inflammation, in exudate, enlargement and fixation of the pelvic organs accompany the other symptoms of infection, abdominal or vaginal section is indicated; not otherwise. If the abdomen is opened the following principles should be observed; remove only infected and necrotic structures; tie the bloodvessels separately; let the broad ligaments gape to drain the pelvic connection tissue; put a curved glass drainage tube into Douglass's pouch, from above, pack the whole pelvic cavity with gauze with the patient in the Trendelenburg posture and the rest of the abdominal cavity walled off with gauze pads; remove the pads; close the wound carefully and seal it; suck out the glass tube once a day for four or five days, with every aseptic precaution; remove it; withdraw the gauze gradually, beginning about the fifth or sixth day, and getting it all out on the tenth or eleventh. You have seen a number of women saved by this technique in spite of a most discouraging pelvic condition. You must take my word for it that no other plan will give as good results. I have tried many other methods in the past and failed. Many cases of infectious salpingitis of less severity than the acute streptococcic variety have been treated by salpingectomy without drainage. Several interesting cases have been presented to you illustrating the differential diagnosis between ectopic gestation, cornual gestation, and inflammations of the uterine appendages. One case admitted to my service was ensanguine. The blood was flowing steadily from an erosion in the ectopic gestation sac near the uterine cornu. The woman's life was saved by an immediate operation. An hour or two more would have given her ample time to bleed to death. A commentary on the proposition to wait for reaction in these cases before operating!

Finally, the rarer complications of the puerperium requiring surgical treatment are diastasis of the recti muscles, coccygodynia, and floating kidney. Separation of the recti muscles is rare if an abdominal binder is carefully adjusted by a competent nurse and tightened progressively with the involution of the uterus. Its treatment when encountered is a binder, massage, electricity, and gymnastic exercises for some weeks, if the patient can afford it. A radical cure is always possible by Webster's operation, which you have seen. Coccygodynia should be allowed six months for a spontaneous recovery, unguentum iodi and petrolatum being applied from time to time over the coccyx. Coccygectomy is indicated if the disease persists and demands relief. You have seen this operation also in the clinic.

Floating kidney as a sequel of childbirth is usually accompanied by ptosis of the other abdominal viscera due to a relaxed abdominal wall. It requires the same palliative treatment as diastasis of the recti muscles. If it resists other treatment Edebohls's operative technique will cure it.

A PLEA FOR MORE SANATORIA FOR THE CON-SUMPTIVE POOR IN ALL STAGES OF THE DISEASE.*

By S. Adolphus Knopf, M. D., New York.

Without depreciating the value of climate as a precious adjuvant in the treatment of tuberculosis, I state that the sanatorium treatment, also known as hygienic and dietetic treatment in special institutions and in many homes, is feasible in nearly all of our home climates; but, alas! not in all homes. Therefore, I wish to say that, while advocating the treatment at home for those who cannot or those who do not wish to enter an institution, I plead with all my heart and with all the earnestness I am capable of with you physicians and through you with your wealthy philanthropic friends or patients, and the legislators of our own and all the States of this great land, for the establishment of more State and municipal sanatoria for the treatment and care of the great number of consumptive poor in all stages of the disease who by reason of their unhygienic environments or extreme poverty cannot be treated at home.

In face of the indisputable fact that tuberculosis is a curable disease, it should be a matter of deep humiliation to our statesmen, municipal authorities, and philanthropists that there are at this moment thousands and thousands of our fellow citizens suffering from tuberculosis, many of them in the prime of life, and that they must continue to suffer and die not because their disease is incurable, but because there are no places to cure it.

It is my intention to embrace the opportunities offered to me as professor of phthisiotherapy of this great institution to appeal to the physicians coming to us from all over the United States, from hamlets, towns, and cities, to enlist every one as a crusader against the great white plague in their respective homes. I trust that the physicians having attended the lectures on phthisiotherapy at the Postgraduate Medical School and Hospital will all become apostles of the gospel of the prevention and curability of tuberculosis, and that they will forever bear in mind that the crusade is one against tuberculosis and not against the tuberculous, for we as physicians must never allow phthisiophobia to become the result of the antiphthisis campaign. On the contrary, we should forever preach and put in practice the principle that the honest, conscientious consumptive, taking care with his expectoration, is not a source of infection, and is as safe an individual to associate with as anybody else, and that he should be treated with the utmost kindness and consideration.

Those who as official authorities or private citizens oppose the establishment of sanatoria or special hospitals for consumptives must be convinced of their error. Show them the great educational value of a sanatorium for consumptives. Tell them that any patient who has been in a sanatorium, if even only for a few months, must of necessity on

account of the training he will have received become a hygienic factor in the community to which he may return, improved or cured. If this simple assurance does not suffice to convert them from their unjustified prejudice against the establishment of a tuberculosis institution, show them the statistics of this country and Europe, which prove that the mortality from tuberculosis among the inhabitants of villages or towns where sanatoria for the tuberculous are situated has always been considerably reduced after the establishment of those institutions. The cleanly and sanitary habits involuntarily imitated by the villagers have resulted in diminishing consumption in their own midst. Thus the well conducted and well equipped sanatorium for consumptives serves not only as an institution to cure, but also as an institution to prevent the spread of consumption. It can even be demonstrated that the prosperity of the community which harbors a sanatorium for the consumptive poor has always been improved thereby. By the cures accomplished in such a sanatorium, wealthy invalids are almost invariably attracted to the locality.

To prevent the spread of consumption by teaching practical and feasible hygiene, to overcome the prejudice against institutions for the treatment of the tuberculous and the prejudice against those who are afflicted with the disease, to cure when cure is possible, to do what we can to arrest the disease, prolong life and render comfortable when absolute cure seems impossible, to relieve the sufferings of the consumptive individual, be it mental, physical, or social, should be our only aim as true workers in the field of modern phthisiotherapy.

16 WEST NINETY-FIFTH STREET.

THE SIGNIFICANCE OF A BLOOD ANALYSIS IN APPENDICITIS.

Can We Depend upon the Leucocyte and Distinctive Polynuclear Counts as a Positive Indicator for or against Immediate Operation?

> By C. C. Sichel, M. D., New York.

Attending Surgeon, Washington Heights Hospital.

There is probably no subject on which more has been written than on when to operate in appendicitis, a subject of vital importance to the general practitioner as well as the surgeon; and yet it remains a much mooted question.

The solution of this question, I believe, lies in the province of the pathologist, the careful study of the blood. The writer of this communication, having found in every case of appendicitis a typical blood picture, makes a special plea to all those coming into frequent contact with cases of appendicitis to give the blood count a careful study. The diagnostic value of a leucocyte and polynuclear counts in this paper has been based on the study of some fifty odd cases.

Although there is much yet to be done in the study of the blood, when infection is present in the human body, and beside the fact that locality, virulency, and stage of infection are known to show widely divergent results in polynuclear and leuco-

^{*}The concluding remarks of Dr. Knopt's mangural address as professor of phthisiotherapy in the New York Postgraduate Medical School and Hospital. The address has for its title How to Adapt Sanatorium Methods to Treatment of Consumptives at Their Homes, and was delivered before the Clinical Society and matriculates of the sanath June 19, 1908

cyte counts, still, when an infection is present, and absorption starts in appendicitis, blood change will Furthermore, absorption in inevitably take place. this condition is the rule, and only in old cases with dense adhesions might there be an exception. say might advisedly, as even these cases show typical blood findings, for though the infection may be walled off from the peritonæum, it is not so thoroughly so from the circulation.

With the start of infection in appendicitis, the blood picture is similar to those seen in infections elsewhere, except that the counts are not always as

high as those in other localities.

Leucocytosis varies from 12,000 upwards, sometimes reaching 25,000 to 30,000. Polynuclear counts show eighty per cent. to above ninety per cent., usually in the neighborhood of eighty-three per cent. One or two per cent. eosinophiles are found early in the attack, but often disappear in later examinations to return when the source of infection is removed. In fact, the reappearance of the eosinophiles is a sign of improvement in the patient's condition. In reference to the latter, however, at least 400 or 500 cells should be counted.

It is not in the well developed cases of appendicitis, after perforation or abscess formation, where the physical signs of the patient make the picture clear to the physician, that blood examination will be of the most service. It is at the beginning of the case, or in those cases where the symptoms are masked, that blood analysis will positively indicate

or counterindicate operation.

It is in this class or state of appendicitis that often a marked absence of alarming symptoms will give the physician a sense of security, will induce him to believe that a mild enteritis or catarrhal condition There is no greater of the appendix is present. chance of error, often fatal error, in the whole gamut of ills to which the human body is heir.

How many cases are seen daily, where there is general abdominal pain, of greater or less severity, with tenderness in the right iliac fossa, with little or no other symptoms? And let me state here there are many of these cases with very little or no rigidity or tympanities, temperature no higher than 100° F., with leucocytes of over 15,000 and distinctive polynuclear counts above eighty-four per cent. It seems there should be more pronounced temperature, with fairly high blood counts, but, nevertheless, there often is not.

How many of these cases have we seen that in twenty-four hours result in abscess, perforation, peritonitis, and often death? These are the cases in which the blood findings will indicate immediate operation. These are the cases in which we need not wait to see whether there is on a second examination an increased leucocyte count or polynuclear percentage. With the first leucocytosis, and increase of the distinctive polynuclear percentage, operate.

I realize in placing this absolute diagnostic value to the blood picture in cases of appendicitis I shall meet no little opposition. However, in all my cases, the blood findings have been diagnostic, and this valuable aid to diagnosis has been a source of great satisfaction to me.

The following are a number of cases, particularly bearing on this subject, which the author wishes to report, as they diverge from the ordinary run of

Case I.—Mr. I. L.; nativity, Italy; age, twenty years. Previous history: For the past three months patient had had pains through the abdomen which increased in proportion with the patient's work

Present history: Pain became sharp and localized about McBurney's point on the day previous to being brought to the hospital. On admission, the temperature was 99.2° F., pulse 70, respiration 22. Abdomen not distended or tympanitic, and but slightly rigid over the right rectus, tender on pressure over McBurney's point; no nausea, no vomiting; bowels constipated. Blood count: Leucocytes, 21,000; distinctive solvanders girkty research received in the control of th

distinctive polynuclear, eighty per cent.; eosinophiles, one

Operation: Appendix distended and adherent to the pos-terior abdominal wall. There were two diverticulæ in the appendix, each containing an enterolith; appendix removed by circular cuff method, after carefully separating adhesions; no drainage. Patient made an uneventful recovery.

Case II.—Mr. J. C.; nativity, Italy; age, twenty-one

Previous history: Four days before admission pains started in the epigastric region, with nausea, vomiting, and constipation. Pain localized at McBurney's point. On admission, temperature was 100.6° F., pulse 100, respiration admission, temperature was 100.6° F., pulse 100, respiration 24. There was some tenderness at McBurney's point, with slight rigidity of the right rectus. Blood count: Leucocytes, 23,000; distinctive polynuclear count, eighty-one per

cent.; eosinophiles, one per cent.

Operation: Appendix found tightly adherent to the lateral abdominal wall, distended, and full of pus. were broken up, appendix removed by circular cuff method; abdomen drained. Patient made an uneventful recovery.

CASE III.-Master W. L.; nativity, United States; age,

fourteen years.

Previous history: Had had the ordinary diseases of childhood, with frequent attacks of gastroenteritis. Considerable pain in the abdomen for three or four days be-

fore admission.

On admission there was severe pain all over the ab-domen, with marked tenderness at McBurney's point. Bowels constipated. There was no distention, but moderate rigidity of the right rectus. Temperature was 101.1° F., pulse 112, respiration 24. Before operation, temperature fell to 90° F., pulse to 100, respiration to 23. Blood count: Leucocytes, 19,000; distinctive polynuclear count, eightytwo per cent.; eosinophiles absent.

Operation: Appendix was found running upwards and

backwards, the tip adherent to the posterior abdominal wall beneath the liver. The appendix was over seven inches in length, distended with pus, which was pointing at one or two places. Adhesions were fairly dense. It was removed by the circular cuff method, and the abdomen drained.

Patient made an uneventful recovery.

Attention is called to the fact of the general improvement of the symptoms in this case before the

operation.

All the other cases follow along similar lines, the diagnosis indicated by blood pictures being confirmed by operation. All cases that showed a leucocytosis and a polynuclear increase were operated on, without finding a single case in which there was a purely catarrhal condition. All interval cases or those not showing a leucocytosis, etc., which were operated on showed that no acute process was in progress.

The author of this communication strongly advocates operation as indicated by blood findings in all cases of appendicitis. When leucocytosis and polynuclear increase is present, operate at once. there is no increase in the counts watch the blood picture in repeated examinations and be guided by the findings plus the patient's general symptoms.

The author wishes to thank Dr. G. Reese Satterlee

for the blood work done in these cases. 50 WIST SIVENTY-SEVENTH STREET.

THE MANAGEMENT OF CHRONIC ENDOCAR-DITIS DURING THE STAGE OF COMPENSATION.*

By Sydney A. Stein, M. D., New York.

Profound interest has been manifested in the diagnosis, treatment, and prognosis of heart disease, and especially of valvular heart disease, by all prominent clinicians since the very earliest attempts at physical diagnosis, thus proving its eminent importance in the practice of medicine. No branch of medicine has been less affected by modern preventive medicine, bacteriology, and serum therapy, yet in the last twenty-five years an enormous amount of literature, of great value to the practising physician, on both the diagnosis and treatment, has been produced. With the bacteriology and other ætiological factors, it is not in the province of this paper to deal.

After all, what is compensation? Briefly, it is that state of the circulation in which a physical defect of the heart has been so corrected as to enable the heart to perform its functions normally. All

compensation is, of course, relative.

In the management of all cardiac diseases there are a few general and special considerations entering into every case. Alcohol is a chronic heart poison; its use should be prohibited or limited, unless specially indicated. Tobacco, tea, and coffee are milder poisons; their use should also be limited or interdicted. Hygiene and hygienic laws are of importance in health, but still more so in disease, and the same care and attention paid to fresh air and diet that we give in tuberculosis must be given in these cases; save with this difference, that cardiac disease is more apt to attack the robust and otherwise apparently strong than is tuberculosis. Therefore, we may have the obese cardiac. To reduce superfluous adipose tissue and thereby render breathing and heart's action easier if often extremely difficult. The fat renders such patients peculiarly liable to attacks of angina, and flesh reduction is safely accomplished only by the greatest care in diet, exercise, and drug treatment.

It is a matter of course that all complicating diseases be treated, but, as any disease or disturbance of function is liable to complicate cardiac trouble, I will content myself with mere mention that the digestive organs, the lungs, the kidneys, and all the emunctuories must be kept in the best possible condition. The nervous system is peculiarly liable to disturbances, the necessary shock of hearing that they are sufferers from an incurable disease, the dread of sudden death, which, among the laity, is believed to be so frequently an outcome, the disturbances arising from the malnutrition of the central nervous system, all tend to subject them, in a marked degree, to hysteria, neurasthenia, and mental instability, which occasionally leads up to in-

sanity.

Rest in the recumbent position, and sleep, are the only two means by which the work of the heart can be reduced physiologically to its natural minimum. It is, therefore, imperative that the period of rest, no matter what method of treatment is being pur-

sued, must be much longer than that which the normal individual requires. They should rest in bed nine hours out of the twenty-four, more if possible. Sleeplessness is due to an infinite variety of causes, yet may often be corrected by simple measures, e. g., if due to flatulence or gastric disturbance, by eating only the lightest and most digestible food at night; on the other hand, some are relieved by eating immediately before retiring a light meal of some sort, such as a cup of milk or chocolate, a glass of kumyss, or a scraped meat sandwich. Hydrotherapy here is of great assistance, both as a hypnotic and as a regulator of cardiovascular condi-The cold pack, full hot bath, the Nauheim baths with carbonic acid gas, can all be given to patients in their homes without the aid of extensive apparatus or trained intelligence. All that is requisite is a little explicitness in directions as to the temperature, length of time, and method of giving bath. Finally, we may be compelled to resort to drugs. Of these, codeine, in combination with one of the urea group of hypnotics, is most generally useful. The bromides may be of service, but must not be too long continued on account of the danger of upsetting the digestive organs and their generally depressing effect; the sodium and ammonium salts are preferable to the potassium as being somewhat less depressing. Chloral is well borne when compensation is good, and is very efficient, but the danger of the habit must be kept in view. trional veronal group will, however, in most instances, serve our purpose. As a last resort morphine may be required, and is, of course, especially efficient in cardiac disease.

Aside from the special and general considerations already mentioned, there remain two great factors in the treatment of chronic endocarditis. These are the heart itself, its special lesion and muscular condition, and second, the condition of the arteries. The arteries themselves, whether contracted or not, their tension, and the amount of blood pressure, are important elements both in prognosis and treatment. Blood pressure is rarely raised above the normal in uncomplicated heart disease, save in aortic insufficiency, in which there is frequently a marked rise above the normal during systole, with a rapid fall below the normal during diastole; and in some cases of hypertrophy. Yet the arteries, by their condition of contraction, may give rise to considerable additional work to the heart muscle. It is therefore a good rule that, as nearly all the cardiac stimulants act as vasoconstrictors, one of the vasodilators mentioned below be given in combination with them. Of these there are two groups, the iodides and the nitrites. The iodides, in addition to their dilating power, act also by decreasing the viscosity of the blood, and as absorbents of chronic inflammatory products, at the same time diminishing, or, at any rate, retarding, the arteriosclerotic processes, which so often complicate chronic endo-The principal iodides in general use are the sodium and potassium salts, and some of the newer proprietary drugs. They may be given almost continuously for long periods, the sodium salt preferably, and in cases of special idiosyncrasy one of the proprietaries may be substituted.

Of the more active vasodilators, amyl nitrite, ni-

[&]quot;Real before the Metropolitae Medica" Some

troglycerin, and sodium nitrite are the most efficacious. The first should only be used occasionally
when rapid action is necessary. When demanded,
its action is much enhanced by the subcutaneous
use of morphine. Nitroglycerin is also a powerful
dilator and stimulant. The latter action is rather
a drawback than an advantage in a compensated
case, when its use should never be long continued,
overstimulation leading to rapid heart action, and,
finally, to irregularity. For continued use the nitrites of sodium and potassium in small doses are
most valuable and least dangerous. I have prescribed them for a month at a time without any but
beneficial results.

The therapy of the heart itself falls naturally into two divisions. The first, and of least importance in the stage of compensation, is drug therapy; the second, treatment other than drugs, especially hydrotherapy and physical therapy. In regard to drugs, those directed to the heart muscle are either stimulant or sedative. Of the former, the least said the better. They are rarely useful and often harmful. There is no more pernicious practice than that which is still too prevalent of prescribing digitalis, strophanthus, convallaria, or strychnine in every case of chronic cardiac disease. Their long continuance is like perpetual goading to a horse. When the real time for their use arrives, like the blows. they have lost their effect. The other group of drugs, the cardiac sedatives, is of great value, and its usefulness very wide, and, I think, in many instances, somewhat neglected. The most important is opium and its derivatives. Since Albutt's classical essay in 1869 on the hypodermatic use of morphine in chronic endocarditis, the powerful stimulant and sedative action of small doses of morphine has been widely appreciated. But the great danger of habit in its constant use has made it important that for ordinary sedative action a less dangerous substitute should be at our command. This we have in codeine, the most useful single drug in the treatment of heart disease in the stage of compensation. It may be given for almost any length of time in small or large doses, and yet the patient not become addicted to it. I have given it almost steadily for two years to a diabetic, and then stopped suddenly without any evil effect. In heart cases I have given it for months at a time without the formation of a habit.

Lastly, we will speak of the mechanical treatment of compensated heart disease. In this I will include all treatment other than drugs - hydrotherapy, Nauheim baths combined with passive motion or massage, and exercises, varying from light calesthenics to the severer forms recommended by Oertel, with the purpose of maintaining compensation. With regard to the Nauheim baths, which are especially useful in hearts with weak muscle and beginning dilatation, I shall not go into details, as they have so recently been ably presented to the New York medical profession by the late Dr. Newton Hememan. His papers were followed by a lengthy discussion on the subject in all our Amertreatment acre explained in a paper written by a member of this society and discussed here.

The method of choice from amongst these me-

chanical means must be influenced by age, physical condition, and social status of the patient. At both extremes of age, naturally, the severer forms of exercise are excluded. Before the age of puberty there is nearly always present a strong tendency to rapid hypertrophy, and frequently, as rapid a degeneration of the hypertrophied muscle, making the prognosis bad in most of these cases, so that the physical activity and restlessness should be curbed rather than added to. At the other extreme, overexertion, being less likely to occur, and activities being naturally lessened, once compensation is established, the natural hygiene of old age will be that of the accompanying endocarditis, which is, as a matter of experience, very well borne.

In between these two extremes, we have, afflicted with chronic valvular troubles, individuals of every variety of physical status. Up to the present time, we have had comparatively little to guide us with regard to the variety, or, rather, the severity of exercise to which a well compensated heart muscle should be subjected, in order to retain what has been gained, in many instances, entirely by the ef-

forts of nature.

Modern instruments of precision, the manosphygmograph, the sphygmograph, and the orthodiagraph combined, have placed within our hands the means of testing the blood pressure and size of the heart during rest, and we can test, at any rate, with a fair degree of accuracy, the functional power of the heart. Every heart, normal or otherwise, on continued severe exertion, reaches a stage when compensation fails, and even, on extreme overexertion, death can take place in asystole. Functional tests are not only useful in diagnosis, but I have endeavored to use them as a means for testing the limits of exertion to which an individual with compensated valvular disease should be subjected.

For this purpose I have used the test proposed by Gräupner, of Nauheim, which is based upon the following phenomena: Given a normal heart, subject it to moderate exertion for a short period of time, and the result will be as follows: First, there is a rise in frequency of the pulse rate; coincidently there is a increased force, and, when measured, an increase of the blood pressure. If the exertion is continued, there is a further acceleration of the pulse rate, coincident with which there is a fall in blood pressure. If at this stage exertion is stopped there is a gradual retardation of the pulse rate, and gradual increase in the blood pressure, which increase is maintained and continues to even beyond the normal after the pulse has returned to its normal rate. This increase does not ensue on extreme overexertion or in functionally weak hearts, or in any heart strained beyond its natural powers. We know that a dilated heart muscle will respond to physical stimulation, as in the passive motion or massage in the Nauheim treatment, so that, if we take a patient with compensated heart disease and subject him to a series of tests of increasing severity, we can accurately determine the grade of exercise to which his heart will respond by a normal increase in blood pressure. Such exercise can only be useful in maintaining the nutrition of the heart. I think we have by this method a test whereby we can make a selection on a little more than empiric

grounds of the form of exercise which we should give the individual. In this way we can determine whether we can employ gentle massage and passive motion in the borderline cases just on the verge of failing compensation, or go on up to graduated hill climbing or calesthenics in those cases which have good compensation and good heart muscle with good reserve force. In testing the functional power of the heart by blood pressure measurements the usual clinical methods of the effects of exercise, on pulse, breathing, and the ratio of pulse and breathing, and especially the effect on the area of cardiac dulness, are of paramount importance, of recognized value, and must not be neglected. No instruments can replace clinical acumen and medical sense, yet these instruments are aids which help us in eliminating certain errors to which the tactile sense, sight, and hearing of all human beings are liable, and it is the sum of the findings of ordinary clinical methods plus instrumental methods which will add to our accuracy, both in our diagnosis and, what is more important to the patient, in treatment.

To conclude this short résumé of our present methods of maintaining cardiac compensation, during the past twenty years enormous advances have been made in the treatment of chronic diseases. tuberculosis has become not nearly so hopeless as heretofore in our estimation, diabetics have their lives prolonged, tabetics have been made to walk again; these successes have been accomplished by painstaking attention to the smallest details of treatment and of methods of living-but in no chronic disease is the importance of individualizing more marked than in the one under discussion this evening. Every patient reacts differently to drugs, to dosage, to different preparations of the same drug, and to the different forms of mechanical stimulation. Care and attention to all these factors will find our efforts amply rewarded by prolonging the life, the ease, and pleasure of living of our pa-

158 EAST SEVENTY-SECOND STREET.

A PRACTICAL CONSIDERATION OF DELIRIUM TREMENS, WITH SPECIAL REFERENCE

TO ITS TREATMENT.*

By Walter T. Dannreuther, M. D., New York,

Assistant Surgeon, St. Bartholomew's Clinic; Assistant Gynecologist, West Side German Dispensary.

Delirium tremens is a condition perhaps infrequently encountered by the average practitioner; yet all of us will occasionally be required to deal with an alcoholic intoxication, either as an entity in itself or as a complication of some other condition, medical or surgical, which, if improperly managed, may develop delirium tremens. Many of our patients are addicted to the habitual use of alcohol, and delirium tremens being only an incident in the course of a chronic alcoholism, it is distinctly to our advantage to recognize the premonitory warnings of this condition and institute proper prophylactic treatment, rather than be com-

Read before the Triprofessional Medical Society of New York City, June 16, 1908.

pelled to fight the disease itself. The treatment of the latter is necessarily radical, and this, together with the extreme gravity of delirium tremens, may seriously embarrass our efforts in other directions.

In a series of one hundred and four cases of delirium tremens, and a large number of instances in which it seemed imminent unless speedily checked. I have had an opportunity to test various methods of treatment and analyze the results obtained from each. This disease will always have a high mortality, in spite of any method of treatment, but by classifying our cases clinically and prescribing accordingly the mortality may be materially reduced.

cordingly the mortality may be materially reduced. We must remember that in a chronic alcoholic patient delirium tremens may be precipitated in one of two ways: either by a temporary excess or by the abrupt withdrawal of alcohol. I have found the latter to be by far the most common cause, which is particularly of note because we are so apt to forget it. This is especially true in hospital practice. A patient may be accustomed to take a considerable amount of alcohol daily without ever becoming "drunk," but if suddenly and entirely deprived of it may develop delirium tremens. It has been my experience that this is the cause of the majority of cases, and usually the physician is, although unintentionally, the most important factor in their development. For instance, suppose we see a case of rheumatism in a patient who is an habitually heavy drinker. Naturally, the first order given is restricted diet and total abstinence; or suppose the same individual is admitted to a hospital with a fracture of the femur; he is confined to bed and his accustomed daily amount of "stimulation" cut The result is the same.

The clinical picture of delirium tremens is well described in all the textbooks. But there has been a marked dissimilarity between the clinical picture of the textbooks and the clinical manifestations in the greater number of cases that have come under my observation. Only a relatively small number of patients demonstrated the commonly described hallucinations. For convenience, let us divide our cases into three clinical groups:

I. Those that evidence prodromal or warning symptoms, the attack itself having not yet developed; characterized by restlessness, apprehensive feelings, tremor, depression, insomnia, anorexia, constipation, and a coated and tremulous tongue. These symptoms may be present for a day or two, and then gradually merge into those of one or the other of the two groups following. Or the patient may recover without a true attack having been developed.

2. Those in which delirium tremens itself has appeared, but are melancholy and comparatively quiet; characterized by unconsciousness, increased tremor, talking or mumbling incoherently, picking at the bed clothes, cold sweat, muttering delirium, dilated pupils, and incontinence of urine and fæces. There is usually some elevation of temperature, and the pulse is soft and rapid. This is the clinical picture the majority of cases present, and by far the most common type of the disease.

3. Those that appear maniacal; characterized by incessant talking, constant insomnia, paræsthesia, illusions, hallucinations of sight and hearing, wild

shrieking, struggling, and maniacal delirium. The temperature may rise as high as 104° F., and the pulse is rapid and of high tension, as a rule. This is the ordinarily described, but most infrequently occurring, type.

Either of these last two types may persist for from three to eight days, at the end of which time the symptoms will either gradually abate, or there will be a reaction with softening and compressibility of the pulse, pulmonary cedema, cardiac fail-

ure, and death.

Few of the textbooks mention the complications of delirium tremens. Osler states that pneumonia often precipitates an attack. But I have observed that when these two occur together, delirium tremens is generally the primary disease and pneumonia the complication. This was noted in thirty-six of my one hundred and four cases. Acute nephritis is another disease to be constantly on guard for. Usually there is also something present which has necessitated the patient's confinement to bed and deprivation of alcohol; this may be an accident, injury, or disease.

Delirium tremens will always tax the skill and judgment of the physician, for although good nursing is absolutely essential, the proper choice of remedial agents is of equal importance. The fact that warm weather tends to increase the mortality

should be given due consideration.

Never forget that we are dealing with a cardiovascular system far below par in delirium tremens. This point cannot be too strongly emphasized. Three of my patients died in an almost identical manner. In each instance the symptoms had apparently cleared up, the mind was clear, and the patient was allowed to get up. Each had been out of bed for from three to five days, and was permitted to not only walk about, but to even do light work in the hospital ward. And each one suddenly laid down on his bed, the pulse gradually softening and weakening, and died within ten minutes, in spite of all attempts to revive them. These cases were an object lesson to me which I shall never forget. I am firmly convinced that had I kept these patients in bed for a week during convalescence and enforced complete rest these deaths would not have occurred.

The treatment resolves itself into that appropriate for each of the three clinical groups re-

spectively.

I. The treatment for this group should be essentially prophylactic. If the patient is an alcoholic, allow him a certain amount of alcohol each day, irrespective of any injury or other disease being present. This amount may be gradually decreased as the nervous symptoms clear up. Give 20 grains of compound jalap powder, with 5 grains of calomel, immediately, and follow with half an ounce of magnesium sulphate in the morning. The patient should be isolated in a light, airy room, if possible, and his mind diverted from himself. The diet, on general principles, should be nutritious and easily digested. The details of the diet will depend largely on any other coexisting condition. The bladder should be carefully watched and catheterized every eight hours if the patient does not void. Al lowing the bladder to remain full for any length of time may cause a reabsorption of toxines. I have experimented with four methods of treatment which have been considered appropriate for this stage: Large doses of digitalis; morphine and hvoscine; bromides and chloral; and strychnine and digitalin. I have never observed that a patient derived any benefit from the large doses of digitalis, at one time so strongly recommended. I gave this method a fair trial, and the result was either a cumulative action of the digitalis or over stimulation of the heart, with an undesirable reaction necessarily following. I shall disregard this method hereafter, as I do not deem it worthy of further consideration. The morphine and hyoscine combination is too radical for this stage. I have proved to my own satisfaction that the bromide and chloral mixture will prevent a larger number of these cases from further development than any other method, but of the cases that do develop, a greater proportion die. When using this combina-tion I generally give 5 grains of sodium and 5 grains of potassium bromide, with 15 grains of chloral, every four hours. More chloral than bromides, because a cerebral rather than a nervous sedative effect is to be desired. When the patient's general health is good I have found this to be a very satisfactory plan. The dose is to be repeated every four hours until the desired effect is produced. If, however, the patient's condition is poor, and the heart not what it should be, I have found the strychnine and digitalin combination efficacious; 1/30 of a grain of strychnine sulphate and 1/100 of a grain of digitalin, by hypodermatic injection, with half an ounce of whiskey by mouth, every four hours. As the patient improves, the strychnine is reduced to 1/60 of a grain, then eliminated, followed by cutting out the digitalin, and finally the whiskey is gradually withdrawn. A larger proportion of patients so treated will suffer from a true attack than with the bromide and chloral mixture, but the mortality is materially re-Provided there is no other serious associated condition, I must confess that I would favor this mode of treatment, as the attack, should it come on, is usually mild, and the majority of cases recover. The emunctories should always be kept active. If the condition is due to an excess, it is well to give 1/10 of a grain of apomorphine hydrochloride as soon as possible, to empty the stomach of all the alcohol, as well as any other débris it may be accommodating.

2. Good nursing is a very important item in the treatment of the cases comprising this group. The patient should be kept scrupulously clean, the bed linen changed frequently, and any involuntary excretion removed as soon as possible. Should a bed-sore appear, get a new nurse. The degree of restraint necessary, and the manner of its accomplishment, depends upon individual circumstances. When some one can be in constant attendance, most cases of this class require nothing further. The ordinary "strait jacket" and the restraining sheet covering the whole bed are either insufficient or cruel. If additional restraint is indicated I prefer two adjustable leather wrist bands which may be fastened to the bedstead on each side by means of straps. These allow a limited movement of the

arms, and do not constrict the chest. Should the patient be exceptionally restless, they may be reinforced by ankle bands and straps of the same These patients require nourishment, and the diet should not be too restricted. But we must not forget that approximately seventy per cent. have an associated alcoholic gastritis. Should feeding by the mouth be impracticable, he may befed by the rectum. In fact, where there is a severe gastritis, I prefer to feed this way. The excretory organs must be kept active, but not at the expense of the patient's vitality. The results that I have obtained from the use of the hot pack have been anything but desirable. There is nearly always a cold sweat that serves to dispose of as much waste as the patient's welfare permits. Increasing this quantity puts an extra tax on the heart, which is already overstrained. We should endeavor to give these patients and their nervous systems rest and sleep. It may be often accomplished by generous doses of bromides and chloral, either by the mouth or by the rectum. It is best to begin with moderate doses, and gradually increase them, watching the heart carefully. If this does not produce the desired effect in two days discontinue it. The morphine and hyoscine combination, 1/4 of a grain of morphine sulphate and 1/100 of a grain of hyoscine hydrobromide, by hypodermatic injection, every four hours, will sometimes prove efficient when the bromide and chloral mixture has failed. But don't ever use this method of treatment in the summer months! The mortality is frightful. In warm weather it is safer to employ the strychnine and digitalin as described for the first group. The duration of the attack is lessened and more cases recover.

3. This group demands energetic remedial measures. Left to themselves, the severity and maniacal characteristics tend to run a progressive course. There is a constant extraordinary strain on the heart, which finally rebels, and death soon ensues. Rest is the all important element to be desired. All will require complete restraint; best accomplished by reinforcing the before mentioned straps with a rolled up sheet passed behind the neck, under the arms on each side, and fastened to the head of the bed. Either the bromide and chloral mixture or the morphine and hyoscine combination, in full doses, is indicated. When these measures do not effectually control the situation, I have obtained excellent results from deep ether anæsthesia. This is usually followed by a peaceful sleep and restoration to consciousness, which the patient appreciates so much that he will frequently request that it be repeated. I have often used it as many as four times in twenty-four hours. Every case in which ether was given recovered.

I have endeavored to confine myself solely to the clinical aspects of delirium tremens, purposely avoided theoretical discussion, and have not attempted to elaborate upon the various methods of treatment and physiological action of the drugs used to any extent.

Subsequent to convalescence being established and the patient on the road to recovery, I would suggest that he be confined to bed for at least a

The medication is to be gradually decreased and the diet correspondingly increased.

There will often be an indication for medicinal agents other than those that I have mentioned. For instance, in the presence of pulmonary cedema, atropine and strychnine, in conjunction with cupping, will be found valuable. Occasionally there will be indication for the ammonium salts, ergot, camphor, elaterium, infusion of digitalis, etc. I have found a mixture containing tincture of nux vomica, tincture of capsicum, and compound tincture of gentian very useful for the gastritis.

2030 BROADWAY.

ON SOME BIOCHEMICAL AND ANATOMICAL CHANGES INDUCED IN DOGS BY POTASSIUM CYANIDE.

BY WILLIAM H. WELKER A. C., AND NORMAN E. DITMAN, M. D.,

New York, (Fr. m. t. g. Laboratories of Biological Chemistry and Pathon sy of Colombia University, at the Cologs of Physicians and Surgeon New 1 ork.) I .- Introduction.

In connection with an investigation that was lately conducted by us in this laboratory, on diminished oxidation under certain pathological conditions, it was desirable to ascertain the effects of such diminished oxidation on elimination of various nitrogen containing products in the urine. Potassium cyanide. which induces diminished oxidation, was selected for the purpose, and the six experiments described in this paper were accordingly carried out. These experiments were also intended to furnish fundamental data for investigations of the influence of guanidin, methyl guanidin, creatin, and creatinin under conditions of diminished oxidation. We have conducted preliminary experiments along these lines, and hope to conduct them before long to com-

It had been our intention to carry out several additional experiments before making our data public. but the recent appearance of a paper on this particular subject, which presented results (of only a few experiments) that are not in harmony with those obtained in this study, induced us to publish at once the observations we have made, especially as it will be some time before we shall be able to resume the work in this connection.

2.- Conduct of the Experiments.

Animals and environment.—These experiments were conducted on six dogs by the general metabolism methods used in this laboratory.1 Each animal was apparently healthy and normal in all respects at the beginning of the experiment in which it was used. The form of the cage² in which the dogs were confined was very well adapted to the collection of the excreta and allowed rapid substitution of urine receivers, when vomiting very closely followed the elimination of urine or vice versa. The cage as well as the room was well ventilated.

¹Mead and Gies: American Journal of Physiology, v, p. 106, 1901; also Gies and Collaborators: Biochemical Researches, i, p. 410, (Reprint No. 21), 1903.

*Gies: American Journal of Physiology, NN, p. 403, 1905

*Berg and Welker: Jeurnal of Biology, NN, p. 404, 1906; Welker: American Journal of Physiology, NN, p. 258, 1905

The animals were thoroughly accustomed to their surroundings and apparently contented before they

were subjected to experimental treatment.

Food.—The daily diet consisted of hashed lean meat, cracker meal, lard, bone ash and water. The raw meat was preserved by refrigeration, according to the usual method in this laboratory.' The bone ash was mixed with the food to give the fæces a desirable consistency.

Periods, weights.—In the records of the experiments, each day ended at 11 a.m. Just before that time the animal was weighed and the weight recorded for the day. At that time also the excreta were removed from the cage and urine receiver.

The food was then given.

Injection of potassium cyanide.—The potassium cyanide used in these experiments was a sample of Kahlbaum's purest ("K"). Whenever used, the cyanide was rapidly weighed and a I per cent. solution prepared. This solution was protected from direct light when not in use. Only fresh solutions were employed. The injections were made subcutaneously in the lumbar region. The animals were in no instance put deeply under the influence of the cyanide by the amounts injected.

Analytic methods.-No analyses were made of the food materials used in these experiments, but great care was taken to secure a sufficient supply of each of the various ingredients to last throughout an entire experiment. Uniformity of diet from beginning to end of each experiment was thus assured.

The amount of ammonia in the urine was determined daily in all experiments except the fifth, in which experiment the dog was on a relatively high plans of protein nutrition. In the case of that animal, it was found by experiment that the urine which was preserved with thymol, showed little tendency to undergo change of ammonia content even after several days, and ammonia was accordingly determined in combined daily urines. The remaining determinations were made on "period urines." These period urines were prepared by combining aliquot fractions of the daily volumes. In the case of the first dog the volumes of the "period urines" were so low that they were diluted with equal quantities of water, in order that the usual amounts could be used for the various determinations. The method used for the determination of ammonia in the urine was Folin's.6

Total nitrogen was determined by the use of the Kjeldahl method. The urine was decomposed by means of concentrated sulphuric acid and small quantities of copper sulphate, a method long in satisfactory use in this laboratory. The digestion was continued for thirty to forty-five minutes after the mixture had assumed a true greenish tint. On coolmg, in each case the mixture was colorless.

The alloxuric nitrogen was determined by preliminary precipitation according to the Salkowski' method, I llowed by treatment of the washed precipitate, together with the nitrogen-free filter paper,

Col aborator Brockennod Researches 1, p. 69 (Reprint No. 1).

by the Arnstein method for the removal of ammonia nitrogen, i. e., by adding water and magnesium oxide to the paper and precipitate, and boiling the mixture. To facilitate matters this was done in a large Kjeldahl flask. After all the ammonia had been driven off, the residual nitrogen was estimated by the usual Kjeldahl method.

Urea was determined by the Folin' method; allantoin by the Loewy10 method; uric acid by the Folin-Shaffer method; creatinin by the Folin method.

Summaries of observations and results in the experiments with animals on medium planes of protein nutrition (Tables I-IV.)

Table I.—First Dog.

Preparatory period.—The daily diet of this animal consisted of meat, 97 grammes; a cracker meal, 26 grammes; lard, 20 grammes; bone ash, 10 grammes; water, 225 c.c. The initial weight of the animal was 6.5 kilos. The preparatory period continued for seventeen days.

"The urine of this period contained a small quantity of the liquid portion of the vomit.
"Womited sixteen minutes after injection. A few c. c. of the liquid part of the vomit were unavoidably mixed with some of the

Discussion of the chemical results of the experiments with animals on medium planes of protein nutrition (first and second dogs, Tables

The injection of small doses of cyanide in the case of the first dog (Period II, Tables I and II) caused a decrease in the average daily excretion of total nitrogen in the urine. There was a corresponding decrease in the amounts of all the various forms of nitrogen named in the Tables (I and II), except that of the purin bases, which was increased.

The analytic results for the third period (Tables I and II), in which the daily doses of the cyanide were 3 mgs. per kilo, are not uniform enough to tell a definite or concordant story. The period was perhaps comparatively too short for the full registration of the effects that may have been induced by the cyanide. Then, too, contamination of the urine with vomit may have introduced some of the apparent uncertainties of significance in the results.

In the fourth period, during which the doses of cyanide were $3\frac{1}{2}$ mgs. per kilo, the average daily excretion of total nitrogen was less than that of the first or normal period. This was also true of the various other forms of nitrogen, except the "undetermined nitrogen," which increased in amount in this period. The daily amount of nitrogen in purin bases, which had risen considerably in the first dosage period and fallen in the next, was so small as to be practically nil in the third dosage period.

If cyanide has a tendency, as claimed by previous observers, to increase nitrogenous elimination, we

urine in the receiver. The solid vomitus we afterward when offered to the animal 16 Vomited twenty minutes after injection. Womited seven minutes after injection. The solid vomitus was eaten again, shortly Ate all vomitus late

should expect to find an exhibition of this effect in the fourth period, during which comparatively large doses of cyanide were given, unless the cyanide treatment in the preceding periods had altered the basis for further comparisons. As indicated above, however, decrease rather than increase was the rule, except in the third period. In the after period slight increases in most of the figures in the tables are to be noted.

During the period of cyanide injection in the experiment on the second dog, the average daily quantities of total nitrogen, of the nitrogen of urea, of that of purin bases, and of creatinin, were increased, while the quantities of nitrogen of ammonia, allantoin, uric acid, and the undetermined fraction were decreased.

The average dose of cyanide for this dog was only about 2 mg. per kilo. No vomiting ever occurred, and from all outward appearances the effects of the treatment were much less marked than in the case of the first. In spite of this fact, however, the total nitrogen elimination from this dog increased, but from the first dog decreased, with cyanide treatment.

Histological-First and second dogs.

Microscopical examination of the viscera of these dogs showed the following:

First dog. Kidney-The uriniferous tubules contained a large amount of degenerated cellular matter, which was granular in appearance. epithelium of the convoluted tubules was slightly swollen and irregular in outline, with a few areas of degeneration. There was slight proliferation of connective tissue along the course of the small bloodvessels.

Liver—This was the seat of a degenerative process of irregular intensity in its distribution, with no definite relation to the periphery of the lobule or the central vein. The degeneration was albuminous in type and moderate in intensity-many liver cells being simply the seat of extreme vacuolization. The nuclei were unchanged.

Heart-Normal. Spleen-Normal. Normal.

Second dog. Kidney-There was moderate albuminous degeneration of the tubular epithelium, which was most marked in the convoluted tubules. Some contained casts. There were numerous areas of small round cell proliferation along the bloodvessels and about the glomeruli. A few of these areas were infiltrated with pus cells.

Liver-There was well marked albuminous degeneration, uniform in distribution, with marked vacuolization of the cells. There was no congestion. The nuclei were unchanged.

Heart-Normal. Spleen-Normal. Pancreas-Normal.

²⁸Vomited twenty minutes after injection. Ate all vomitus later.

¹⁹Vomited repeatedly, beganning eighteen minutes after injection, ending fifteen minutes afterward. Ate all vomitus later.

²⁰Vomited eighteen, and again thirty-four minutes after injection. Ate all vomitus later.

²¹Vomited several times thirty minutes after injection. Ate all vomitus shortly afterward.

²²Diarrhoca occurred near the end of the day.

Summaries of observations and results in the experiments with animals on low planes of protein nutrition (Tables V-X).

Table V .- Third Dog. Preparatory Period.

Table showing the decreasing quantities of meat fed the animal daily in bringing it gradually down to a low plane of protein nutrition. (Initial daily diet: Meat, 96 grammes; cracker meal, 32 grammes; lard, 24 grammes; bone ash, 8 grammes; water, 280 c.c.)

| | Body weight, | Weight of meat |
|---------|--------------|------------------|
| Date. | kilos. | grammes. |
| July 10 | 8.00 | 96 |
| July 11 | 8.00 | 96 |

| July 20 | 7.92 | 61 |
| July 21 | 7.86 | 56 |
| Inly 22 | 7.82 | ²⁵ 56 |

The only ingredient in the diet that was subject to quantitative change during the preparatory period was the meat. Two days previous to the beginning of the fore period and from then on to the end of the experiment, the quantity of meat fed daily was 56 grammes. The other ingredients were as follows: Cracker meal, 32 grammes; lard, 24 grammes; bone ash, 8 grammes; water, 280 c.c.

The meat was the only ingredient that was subject to quantitative change during the preparatory period. At the beginning of the fore period, and throughout the whole experiment thereafter, 70 grammes of meat were given daily with the following amounts of the remaining ingredients of the diet: Cracker meal, 40 grammes; lard, 30 grammes; bone ash, 10 grammes; water, 350 c.c.

³⁷The differences between the results of the determinations of the alloxuric nitrogen and the uric acid were so slight as to warrant the conclusion that the uric acid nitrogen was the only purin nitrogen eliminated in quantities sufficiently large for consideration.

[&]quot;About 17 grammes per kilo; approximately 0.6 gramme of nitrogen per kilo.

²⁹About 11.5 grammes per kilo; approximately 0.4 gramme of nurogen per kilo.

³⁰About 8.25 grammes per kilo; approximately 0.3 gramme of nitrogen per kilo; average per lation of the first half hour after injection. Refused all offers of vomitus, but ate the same with the regular meal, on the following da Vomited within twenty minutes after injection. Ate all of vomitus later:

"Vomited about fifteen minutes after injection. Ate the vomitus with the meal on the following day."

Discussion of the chemical results of the experiments with animals on low planes of protein nutrition (third and fourth dogs, Tables V-X).

The average daily total urinary elimination of nitrogen in these two experiments failed to show a concordant tendency. In the case of the third dog (Tables VI-VII) there was a slight increase during the cyanide period, while, on the other hand, there was a decrease in the case of the fourth dog (Table IX-X) during the cyanide period. nitrogen of ammonia was markedly increased in the case of the third dog during the cyanide period (Tables VI-VII), but was diminished slightly in the experiment on the fourth dog (Tables IX-X). The average daily elimination of urea was very slightly increased during the cyanide period in the experiment on the third dog, but in terms of per cent. of the total nitrogen it decreased markedly. During the same period in the experiment on the fourth dog, however, the average daily amount of urea nitrogen, as well as its per cent. of the total nitrogen, decreased decidedly. The other notable result of these two experiments was the sharp increase in the average daily amount of the undetermined nitrogen in each experiment. The remaining results of these two experiments are diametrically opposed to each other.

Histological. Third and fourth dogs.

The microscopical examination of the viscera of these dogs showed the following:

Third dog. Kidney-There was congestion of the cortical area and slight swelling and irregularity of outline of the cells of the convoluted tubules.

Liver-This was the seat of a diffuse degenerative process, uniform in intensity in all parts of the liver lobules. The nuclei were intact, but the cytoplasm was the seat of an extreme albuminous degeneration, which was so excessive that only a few areas of granular cytoplasm remained and the outlines only of the cells persisted. There were irregular areas of congestion.

Heart-Normal. Spleen-Normal. Pancreas-

Normal.

Fourth dog. Kidney-There was slight swelling of the epithelial cells of the cortical tubules, with irregularity of outline. There was a little exudate. Scattered irregularly through the cortex were areas of small round cell infiltration. Most of these areas contained a number of pus cells. They occurred along the course of the bloodvessels, but the glomeruli were not involved.

Liver-There was well marked albuminous degeneration, uniform in distribution, with marked vacuolization of the cells. There was no congestion.

The nuclei were normal.

Heart-Normal, Spleen-Normal, Pancreas-Normal.

Summaries of observations and results in the experiments with animals on high planes of protein nutrition (Tables XI-XVI).

Table XI.—Fifth Dog.

Preparatory period.—Table showing the increas-

ing quantities of meat fed the animal in raising it to the high nitrogen plane.

(The initial diet of this animal consisted of meat, 120 grammes; cracker meal, 32 grammes; lard, 24 grammes; bone ash, 10 grammes; water, 280 c.c.)

| | | Body weight, | Weight of meat, |

| | 21 | 8.31 | 380 |
| July | 22 | | ³⁶ 38n |

The meat in the daily diet was increased twenty grammes each day, excepting on July 12th, 13th, and 14th, ending with July 21st, when the daily amount was 380 grammes. The other ingredients remained constant in quantity throughout the entire experiment.

⁵¹About 16 grammes per kilo; approximately 0.56 gramme of nitrogen per kilo.

[&]quot;No analytical work was done on the urine of this period because of the contamination of the urine with fluid vomit.

SOn this day the bone ash was increased to 15 grammes. All the other ingredients except the meat remained constant.

About 32 grammes per kilo: approximately 1.12 gramme of nitrogen per kilo.

[&]quot;About 43 grammes per kilo; approximately 1.51 gramme of metrogen per kilo.

The daily portion of meat was increased 20 grammes per day ending with October 23d, on which day the weight of meat in the diet was 348 grammes. This weight of meat was fed daily, together with the weights of the rest of the ingredients as specified above, to the end of the experiment. The animal was fed this diet from October 23d to November 2d (eleven days), before the actual observation of normal conditions was commenced.

trogen fell slightly during the period (VII) in which relatively small doses of cyanide were injected, and also during the period in which comparatively moderate doses of cyanide (X) were administered. On the basis of its proportion of the total nitrogen, the urea nitrogen in the urine of the fifth dog fell slightly in the first of the two periods referred to, but rose in the latter period. During the cyanide period of the experiment on the sixth dog (Tables XV-XVI) the urea nitrogen rose in quantity.

The allantoin nitrogen was diminished after administration of comparatively small doses of cyanide in the fifth dog, but was increased after moderate doses in the same animal. The allantoin nitrogen was diminished during the cyanide period of the experiment on the sixth dog.

In the experiment on the fifth dog the uric acid nitrogen was fairly constant throughout, but in the case of the sixth dog the eliminated amount in the cyanide period was larger than that of the first period, while the excreted quantity in the after period was greater than the combined amounts of uric acid nitrogen in the fore period and the cyanide period.

In both experiments, creatinin nitrogen appeared to be diminished by the cyanide treatment.

The "undetermined nitrogen" was but little affected by *small* doses of cyanide in the fifth dog, but was decreased markedly in the same animal after treatment with *moderate* doses of cyanide. The same decrease in undetermined nitrogen ap-

Discussion of the chemical results of the experiments with animals on high planes of protein nutrition (fifth and sixth dogs, Tables XII-XVI).

In both of these experiments the average daily total elimination of urinary nitrogen was diminshed during the periods of cyanide injection. In the experiment on the fifth dog the ammonia nitrogen rose markedly during the period (VII) in which small doses of cyanide were administered (Tables XII-XIII), and increased slightly during the period (X) in which moderate doses of cyanide were injected. There was a similar slightly increased elimination of ammonia nitrogen during the cyanide period in the experiment on the sixth dog (Tables XV-XVI).

In the experiment on the fifth dog, the urea ni-

peared after the cyanide treatment of the sixth dog.

Histological. Fifth and Sixth Dogs.

The microscopical examination of the viscera of these dogs showed the following:

Fifth dog. Kidney—There was marked congestion, with well marked albuminous degeneration of the epithelium of the convoluted tubules. The epithelium was swollen and in places disintegrating. The lumina of the tubules contained a large amount of granular matter. The nuclei were intact. Some glomeruli were much shrunken and were composed almost entirely of connective tissue cells. In the neighborhood of some glomeruli and along the course of some blood vessels were large areas, rather sharply circumscribed, of small round cell proliferation.

Liver.—This was the seat of mild parenchymatous degeneration, slightly more marked about the central vein than in the periphery of the lobule. The degeneration, which was albuminous in nature, was slight and accompanied by very moderate vacuolization of the cells. The congestion was not marked.

Heart-Normal. Spleen-Normal. Pancreas-Normal.

Sixth dog. Kidney-The cortex was much congested and the tubular epithelium was the seat of marked albuminous degeneration, which was most evident in the convoluted tubules. The cells were greatly swollen and granular, and irregular in outline. The lumina contained granular matter. No distinct proliferation of connective tissue could be made out. The glomeruli were normal.

Liver—There was mild albuminous degeneration of the liver cells, slightly more marked about the central vein than in the periphery of the lobule. There was very slight vacuolization of the cells. There was no congestion.

Heart-Normal. Spleen-Normal. Pancreas-

Normal.

Historical.

The first investigation of the influence of potassium cyanide upon nitrogenous metabolism was made by Loewy.35 In a preliminary communication he stated that on the day of poisoning, and on the day after, the nitrogen elimination was markedly increased. The cutput of amino-acid nitrogen also seemed to be decidedly increased.

In a second paper on this subject, Loewys stated that the total quantity of excreted nitrogen did not increase in all cases. He concluded that the plane of nutrition has some relation to the manner in which cyanide affects nitrogenous metabolism. That conclusion is in accord with the prior results obtained by Fränkel and Geppert⁸⁷ in their researches on diminished oxygen supply. tablished a similar relation between increased nitrogen elimination and the plane of nutrition. The increase of excreted nitrogen was always least in fasting animals, and invariably appeared later.

As the first series of experiments in this study were nearing completion, we were informed that a similar investigation was being conducted by Richards and Wallace. Their published results88 do not show any marked difference in the effects of cyanide on two dogs, on different planes of nutrition. Richards and Wallace observed an increase in the total of excreted nitrogen and urea nitrogen, with no increase of ammonia nitrogen in the urine. Creatinin was markedly diminished in the urine on the days of severe poisoning. The un-determined nitrogen increased in the urine on the days of severe poisoning.

Conclusions.

Potassium cyanide, injected subcutaneously in gradually increasing daily amounts from one half to three and a half milligrammes per kilo, through periods ranging from four to twelve days, failed to

*Loewy: Centralblatt für Physiologie, xix, p. 856, 1906. *Loewy: Buchemische Zeitschrift, iii, p. 450, 1907. *Frankel and Geppert. Cited by Loewy, lee. sit. *Richards and Wallace Journal of Biological Chemistry, iv. 1.

cause any marked increase in the total elimination of nitrogen in the urine. In six out of the nine cyanide periods, however, the total amount of nitrogen excreted in the urine was actually diminished. In the case of the three other periods the increase observed was very slight.

Possibly the urinary excretion of nitrogen was not materially increased in these experiments, after the cyanide injections, because the doses were too small to produce convulsions or to cause the associated conditions which may markedly augment catabolism, and which may have been largely responsible for the increased elimination of nitrogen that was observed by some of our predecessors in such studies.

The plane of protein nutrition seems to influence the degree to which subcutaneous injections of cyanide affect the elimination of some of the forms of nitrogen in the urine. A comparison of the results for urea and undetermined nitrogen in the urines of the animals on high and low planes of protein nutrition makes it evident that the percentage of urea nitrogen increased and that of the undetermined products decreased in the urines from the dogs on high protein nutrition planes, whereas the reverse in each case was noted for the urines from the dogs on low protein nutrition planes.

Further work will be necessary before the open questions that remain can be answered with assur-

We wish to express our most heartfelt thanks to Professor William J. Gies for his kind advice and guidance in the conduct of these experiments.

PAROXYSMAL HÆMOGLOBINURIA.

BY EDGAR G. BALLENGER, M. D., Atlanta, Ga.,

Lecturer on Genitourinary Diseases in the Atlanta School of Medicine; Genitourinary Surgeon, Presbyterian Hospital.

Paroxysmal hæmoglobinuria was first recognized by Charles Stuart in 1794, and since only a limited number of cases have been reported, probably less than eighty (Stempel). The symptoms and histories of these patients were so interesting that they have been studied by numerous observers with considerable care and detail, hoping to reach an understanding of the obscure ætiology of the disease.

The following history is so typical and well marked that I think it worth reporting, with a brief review of some of the associated conditions and symptoms of disorders more or less closely related to this form of hæmoglobinuria.

CASE.—Mr. N., a railway contractor, aged thirty-nine, married, was referred to me on account of "blood in the first part of the urine when the patient became chilled."

The family history is as follows: Father living and at the age of seventy and in good health except "dyspepsia";

the age of seventy and in good health except "dyspepsia"; mother living, sixty-nine years of age, and in good health: one brother, two sisters, two half brothers and one half sister all living and apparently well. The patient had had the usual diseases of childhood and suffered much with backache and headache during his youth. There was no history of syphilis, although of seventy-seven cases previously reported twenty-three had unmistakable evidences of syphilis, eight were children with hereditary lues, two of them heigh sisters. of them being sisters.

Gonorrhœa was contracted one year ago, but was en-

tirely cured. Severe jolting caused pain in his sides over the kidneys; sometimes one side, sometimes the other. Fourteen years ago he had iritis and two days later facial paralysis. The patient insisted that the "strong medicine" used for his eye caused the paralysis. Ten years ago he had a band like sensation around the waist for about ten days. There was no pain, but only a feeling of slight constriction. There was sometimes a skin eruption, which resembled the itch (not urticaria). For seven years exposure to cold or the chilling of any part of his body immediately brought on an attack of hæmoglobinuria. No other influence seemed to have anything to do with these attacks, and driving in the cold with the body, legs, and feet warm and only the hands chilled produced the hæmoglobinuria. The attacks were very infrequent during the summer months, but invariably followed distinct chilling, no matter what the season. There were often several attacks a week during the winter, as the duties of the patient frequently subjected him to exposure during inclement weather. An approaching hæmoglobinuria could always be foretold by a feeling of fullness in the gastric region and by considerable eructation of gas from the stomach. After the patient had become thoroughly warmed the urine cleared up within three to eight hours, depending upon the extent and degree of exposure. For several hours there was a feeling of weakness or depression, which he described as being like that which follows sexual intercourse. When this had passed away he felt as well as

usual until further exposure to cold.

The patient's general health was excellent; he was a large, well developed, well nourished individual with a healthy, ruddy complexion and no evidence of anæmia from these frequent losses of hæmoglobin. The urine be-tween attacks was about normal; sp. gr. Lot8, acid in reac-tion, dark amber color, no albumin, no sugar, no casts, no indican; chlorides thirteen per cent, phosphates 0.05 per cent, sulphates 0.04 per cent; microscopically nothing of interest was observed. When first seen during an attack he was requested to void his urine into four glasses; this readily explained the reason for the statement earlier in the examination that the blood only came with the first part of the urine, as a much larger amount of brownish red sediment was passed into the first glass than in the subsequent ones, the fourth having very little sediment, but a clearer reddish look. The amorphous sediment in the first glass formed about one quarter the volume of the urine. An examination for hæmoglobin with freshly pre-pared tincture of guaiacum and old oil of turpentine gave a distinctly positive reaction. Albumin was present in considerable quantity, but no sugar and only a trace of bile and indican. The chlorides were 0.19 per cent., phosphates 0.07 per cent., and sulphates 0.04 per cent. Sp. gr. 1.020; reac-

Microscopically there were observed many hyaline and granular looking casts—the latter being very abundant and probably composed of the brownish amorphous sediment. There were occasional red cells, leucocytes, and epithelial cells. The patient said the urine was always diminished during these attacks.

Dr. J. N. LeConte kindly made the following report of the patient's gastric condition. It is only a partial examination, however, as the patient was extremely unreliable and irregular about returning, and we were unable to carry out many of the tests and examinations that would have made the report of additional value and interest.

The patient had slight recurrent symptoms of indigestion for eight or ten years, which seemed to accompany hæmoglobinuria.

Physical Examination.—Well nourished, thick, firm, abdominal walls, stomach in situ. So far as could be determined, liver, spleen, and kidneys are of normal size and positive.

Ewald-Boas test meal 60 c.c., poorly ground up, free hydrochloric acid to, total hydrochloric acid 28, total acidity 36, considerable mucus in chyme, no occult blood in chyme. Rennin and pepsin normal. Schmidt test diet not yet given. Ordinary formed brown stool, shaped, nothing abnormal except small amount mucus covering first portion of the local blood in against

Patient had deficient gastric secretion and probably mild gastric catarrh.

Cause.—The cause of paroxysmal hæmoglobinuria

causative factor, as has malaria. The latter, however, probably derived this distinction from confounding with the well known malarial hæmoglobinuria. Dapper in 1868 advanced the view that, since mental excitement and nervous irritation sometimes produce paroxysmal hæmoglobinuria, a vasomotor influence is a causative factor. Ehrlich thinks that in these subjects exposure to cold causes the development of "ferments" which dissolve the blood. Others allege that the red cells have an undue susceptibility or lack of resistance to cold. Cold is nearly always the chief provocative factor, although mental and physical exertions are sometimes the cause of hæmoglobinuria.

Clinical Picture.—Stempel' describes, essentially as follows, the general symptoms of typical attacks

of paroxysmal hæmoglobinuria:

The patient is usually pale, anæmic, weak, and poorly nourished, perhaps with a hæmic murmur of the heart, although many of the patients are rather pale, but otherwise well and strong. Beaumetz, Murri, and Kast describe their cases as being of a healthy, rosy color. A light icterus often exists, even in periods between attacks. In the large majority of cases certain prodromal signs precede the attack and enable the patient to foretell with certainty the approach of the hæmoglobinuria. These signs are exceedingly variable, and we find drawing pains in the kidney region (Greenhone, Eichbaum); frontal headache (Rosenbach, Murri); pain in the right breast, liver, and splenic region (Boas and Struburg); pain in the kidney region, anxious feeling about the heart, sense of exhaustion (Potain); belching gas, pain in the region of the stomach (Gillespie); pain in the back and feet (Frazer); shortness of breath, cyanosis, "things turning black before the eyes," drawing in the limbs, feeling of oppression (Wollf); frequently incessant yawning; especially characteristic is a pronounced feeling of ill ness, weakness, and heaviness in the limbs. There is usually a slight acceleration of the pulse, without a rise in temperature. The urine up to this time is clear; in some few patients the presence of albumin can already be detected. The typical attack is almost invariably introduced by chilliness, which varies from a slight feeling of cold to a hard shaking chill; sometimes it manifests itself only as cold feet, numbness of the fingers, or blue coloring of the field of vision (Bristance, Laycook). It is exceedingly seldom that the chilly symptoms are absent. During the shaking chill, or perhaps very soon after it passes off, the temperature rises usually to considerable height, the severity of the attack. of course, causing an extreme variation in it. The liver and spleen may be somewhat enlarged and tender, but pressure over the kidney very rarely produces pain. A short time after the shaking chill the urine assumes its characteristic appearance. quantity of the hæmoglobin varies exactly with the severity of the attack. The color of the urine varies from a delicate rose color to reddish brown, brownish black, or a deep black. The hæmoglobin appears as a brownish red sediment, which under the microscope is seen as an amorphous or granular substance. The urine contains a distinct amount of albumin.

Lectrod let for do terror clouds for Medicin and Chirargie, s. 10 5 to 205 cars.

The specific gravity varies between 1.010 and 1.032: the reaction is nearly always acid. Uric acid and oxalic acid are frequently observed, casts are numerous, the hæmoglobin casts usually most promineutly represented; hyaline, granular, and cellular casts may also be present. Kidney, epithelium, leucocytes, and, occasionally, red cells are found. Bile is said to be seldom found. There is usually a decrease in the amount of urine after attacks. Hæmin appears in paroxysmal hæmoglobinuria, but not to such an extent as is found in the infectious forms. The attack terminates with a more or less free outbreak of perspiration; the malaise fades away, and there remains only a feeling of dulness and relaxa-This description applies to a typical attack, but often the attacks are much milder and many of these symptoms may be absent. Several authors have observed an urticaria coincident with the at-

Blood Changes.—The leucocytes are usually about normal. The alkalinity is slightly decreased, and of course there is a decided decrease in the red cells. but this is likely to be followed by a rise to normal or above in two to six days. Stained specimens during an attack are said not to show the red cells in rouleaux, and many pale and broken cells are observed. The serum may be tinged with brown. In chronic cases there is usually anæmia and splenic

General Considerations.—The coloring matter in the urine is not hæmatin nor always hæmoglobin, but most frequently methæmoglobin. Methæmoglobin has the same amount of oxygen as oxyhæmoglobin, but probably in chemical union, as it is more firmly held.

Hæmoglobinuria is abnormal in man, although normal in certain vertebrates. Osler mentions a peculiar toxic form of hæmoglobinuria which occurs in horses. It appears suddenly and is associated with paresis of the hind legs. Death usually follows an attack within a few hours or a few days. Horses are affected only after being stalled for several days and then taken out and driven, particularly in cold weather.

Raynaud's disease is thought by some observers to be closely related to paroxysmal hæmoglobinuria. When these diseases are found combined the symptoms of either may dominate the clinical picture. Raynaud's disease begins as blotches, symmetrical in arrangement and paroxysmal in character. There is also local syncope, asphyxia, or hyperæmia. Trophic disturbance finally begins as an almost symmetrical dry gangrene. Pain is most excruciating. The disease may exhaust itself in a single attack, or renewed attacks may continue for years. It occurs more frequently in women than men, while the reverse is true of paroxysmal hæmoglobinuria. There is often a decided difference in the temperature of individual fingers. The cause is usually cold or toxic influences-occasionally traumatism or malaria.

Ralfe has noted cases of paroxysmal hæmoglobinuria with the general symptoms of this disease, in which the urine was albuminous and there was an increase in urates, but hæmoglobin did not appear. These, he supposes, are due to the slight effect of the toxic agent and only a few red cells are destroyed, which are taken care of by the spleen and liver, while the globulin is passed out in the urine.

Ralfe also thinks that the so called intermittent functional or cyclic albuminuria may be a precursor of typical paroxysmal hæmoglobinuria.

Paroxysmal glycosuria has also been observed.

In this connection I have collected some of the most common causes of toxic hæmoglobinuria. Blood transfusion from one mammal to another produces hæmoglobinuria. There is also an epidemic form of hæmoglobinuria of new born infants characterized by jaundice, gastrointestinal disturbance, constipation, rapid pulse and respiration, fever, and some-Punctate hæmorrhages occur on times cyanosis. the body, and the urine contains albumin and methæ-Severe burns produce hæmoglobinuria moglobin. and cause a tendency toward the formation of thromboses. Snake poisons induce a rapid solution Sunstroke has been known to of the red cells. cause it.

Among other causes may be mentioned arseniureted hydrogen, if inhaled; poisoning by toadstools, potassium chlorate, chromic acid, carbonmonoxid. pyrogallic acid, antifebrin, hydrocyanic acid, nitrites.

and nitrobenzole.

The Treatment of Paroxysmal Hamoglobinuria. The treatment consists chiefly in avoiding expos ure to cold and in acquiring an immunity to its effect by suitable hardening measures. When possible the patient should live in a warm climate and wear flannels during chilly weather. The therapeutic measures are based upon many different theories according to the view as to its cause. Quinine was administered before it was shown that paroxysmal hæmoglobinuria was not dependent upon ma-Food containing oxalic acid was forbidden by Robin on account of the frequent excessive secretion of calcium oxalate. Tonics, iron, and a nourishing diet are necessary when the patient is anæmic and weak.

The management during an attack is to place the patient in bed and upon a diet of plain warm milk or very bland, easily digested food. Patsch was the first to try a systematic hardening of his patient to increase the resisting power of the blood cells against the influence of cold. For this purpose warm showe: baths were employed, and by degrees the temperature was lowered. In recent times this has been used more successfully by Leyden and Klemperer, who were able to prevent attacks from cold which previously would have brought on a hæmoglobinuria, by the hardening with water and by air. Chvostek gave amylnitrate inhalations, but this plan of treatment did not prove successful in corroborative experiments-probably because the cold was too great to be dissipated by free dilatation of the surface bloodvessels. Bollinger reported an improvement in his patient from a sojourn in the mountains.

Where there is a history of syphilis, mercury and potassium iodide have given very satisfactory results. Striebung and Kwasoway observed a distinct improvement in the general condition and a diminution in the attacks, while complete cure after energetic treatment has been reported by Murri, Götze.

Schumacher, and Kopp.

1004 CENTURY BUILDING.

TREATMENT OF ERYSIPELAS. By Dell B. Allen, Ph. B., M. D., New York,

Assistant Physician to Presbyterian Hospital Dispensary; Instructor in Medicine at Fordham University School of Medicine.

Although all authorities agree that local treatment in erysipelas is of paramount importance and recommend carbolic acid for such treatment yet I am impressed with the general use of weak solutions. Warren Gould recommends one per cent carbolic in vaseline. Stelwagon uses the same strength solution, or a two per cent. creolin solution. my mind these are far too weak to combat the inflammation, kill the germs, or prevent spreading. The most frequent site is on the face without any apparent wound, so called idiopathic erysipelas. Boston and Blackburn (Journal of the American Medical Association, November 2, 1907) analyze a series of 564 cases of which 485 were facial.

Its pathology shows it to be a streptococcic infection of subcutaneous tissue and lymphatics, accompanied by œdema and swelling of the skin, which is tense, red, and very tender, and shows a distinct

line of demarcation.

Although erysipelas is a selflimited disease and tends to spontaneous recovery yet it is dangerous not only on account of its toxic effect on the kidnevs but if the condition spreads above Reed's base line there is danger of its penetrating by the lymphatics into the meninges. In spite of the probability of a spontaneous cure I think we are justified in aborting and cutting short an attack if possible.

My routine treatment is to paint the area with pure carbolic acid extending the painting about three eighths of an inch beyond the line of demarcation. This is allowed to remain until it becomes white when it is washed off with 95 per cent, alcohol. The penetrating action of the carbolic is a direct germicide to the streptococci already present, and the ring around the area serves as a strong barrier beyond which it is almost impossible for the infection to spread. This line of treatment causes an intense smarting and burning which lasts but a few moments and is quickly relieved by alcohol. In some cases the burning continues for an hour or two in which I direct that a cloth saturated with alcohol be laid on the area. In case of extension into the eyelids where it is impossible and impractical to use the pure carbolic acid I prescribe a two per cent. carbolic acid solution in unguentum hydrægyri ammoniatum to be applied frequently.

I can report but twelve cases of erysipelas so far that have been treated in this manner, but the results have been the same in every case. I have never made more than two applications over the same area, one application being usually sufficient. In one case only did the inflammation spread beyond my first frontier. In no case was there fever on the second day and never any delirium. Desquamation began on the average in four days and was complete in another week, making the duration less than two weeks instead of three or four by milder and weaker solutions. The skin under desquarration is pink and healthy and heals without

scarring.

Our Renders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXV. How do you treat cholera infantum? (Closed

June 15, 1908.)
LXXVI. How do you treat acute articular rheumatism?

(Answers due not later than July 15, 1908.)
LXXVII. How do you treat varicose ulcer? (Answers

LANTI. How do you treat various uter? (Answers due not later than August 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not REQUINED) that the answers be short; if practicable, no one answer to contain more than six hundred reach. words.

All persons will be entitled to compete for the prize whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.
All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXIV has been awarded to Dr. Henry C. Becker, of New York, whose article appeared on page 1244 of Volume LXXXVII.

PRIZE QUESTION NO. LXXIV.

THE TREATMENT OF SUNSTROKE.

(Concluded from page 27.)

Dr. R. S. Fitzgerald, of Richmond, Va., observes:

Sunstroke is an affection caused by exposure to severe heat, either natural or artificial. In the majority of cases we have a few premonitory symptoms before complete prostration sets in, such as headache, dizziness, tingling sensations, and nausea; pain in the epigastrium, vomiting, and excessive thirst soon come on. In severe cases there is always loss of consciousness. The patient soon regains consciousness, but there is extreme pallor, rapid respiration, rapid pulse which is soon followed by a slow pulse, temperature goes to 104° or 105° F., or at times even as high as 108° F. The skin is usually covered with a clammy perspiration or may be unusually dry, convulsions often occur, of an epileptoid character, delirium often follows, and the body is either rigid or very flaccid. There is a general congestion of the entire system, lungs, liver, spleen, and brain. The blood is in a very fluid state.

The diagnosis is usually very easy, the history of the case, exposure to the rays of the sun for some time or exposure to other heat especially when the air is humid.

Diagnosis positive, then comes the treatment. First put patient to bed or absolute rest, loosen or remove the clothes. If taken sick on the street or in the field he should at once be taken in the shade, clothes loosened and cold cloths put to head and changed repeatedly, also give some stimulant such as brandy. If patient is in a state of coma strychnine, camphor, and nitroglycerin should be given hypodermatically, morphine and atropine may be given in case of convulsions. If patient can be taken to his home give cold baths or cold packs. with ice, until temperature is reduced. Iced water enema is very effectual for reducing temperature.

Regulate the temperature by a rectal thermometer. In very severe cases free venesection may be resorted to.

Dr. Elias William Abramowitz, of New York, writes:

Prophylaxis.—The amount of work an individual does should be lessened during the warm season, especially if he has once been sunstruck, or is not accustomed to warm weather. In factories, etc., where men work at large furnaces, free ventilation with frequent shifting of men, would militate against heat exhaustion, which also comes under the category of sunstroke. In military service, drills, marches, etc., should be shortened, frequent halts made, and each man supplied with fresh, cool water. The wearing apparel should be of light flannel material and light in color; the best head gear being the helmet lined with green material to keep out the actinic rays of the sun.

The diet should contain as little meat and as much of vegetables as is consistent with the tastes and needs of the individual, fruit juices being especially recommended. Fresh, cool water in small quantities and at frequent intervals is sufficient to keep the tissues supplied with the fluid they require, if the individual perspires freely. It also keeps the bowels regular, thus preventing the accumulation of toxines. Iced coffee and tea are also good. Alcohol should be permitted only in rare instances. One or more cold baths during the day are excellent.

Treatment.—There are three classes of cases: I. Heat Prostration.—This is a mild form of sunstroke in which the patient complains of headache, vomits, and may go into syncope. He should at once be carried to a cool shady spot, his clothing loosened, cold showers given to head and neck, and a cool drink administered. Liquor ammon. acet., floz i-iv; spirit ammon. aromat., floz i-ii; strych. sulphat., gr. 1/40, may be given as stimulants. Rest from twenty-four to forty-eight hours will greatly help to bring the patient around.

2. Sunstroke.—A severer form, in which we get complete circulatory and respiratory collapse and a temperature which may reach 115° F. Here immediate action is necessary. The patient should be stripped and cold applied in any of the following forms: Cold showers, cold packs, cold sponge, or cold spray, using friction all the time. Cold rectal irrigations should be given only in the hyperpyretic form. Care must be taken that the temperature does not fall below 102° F. Antipyretic remedies are not advised, because of their depressant action. After this treatment the patient should be dried, placed in blankets, and a strong purge given. Oxygen and artificial respiration should be resorted to if asphyxia occurs. For stimulation, camphor, ether, or whiskey hypodermatically are recommended. Digitalis, strychnine, quinine should be used with caution. If convulsions occur, chloroform inhalations should be given. If the pulse is full and bounding, and the patient is cyanozed, phlebotomy is advisable; veratrum viride is also recommended. Diet in these cases should be liquid, followed later by cereals, eggs, etc.

3. Heat stroke.—An exhaustion that occurs in stokers, engineers, etc., and not due to the direct rays of the sun. Symptoms coincide with sunstroke, but instead of pyrexia there is apyrexia. Envelope the patient in hot blankets and use same stimulants as in sunstroke. Do not use cold in these cases.

After treatment.—"Once sunstroke always sunstroke." Hence residence in a cool climate is preferable for one who has had sunstroke. While the patient may convalesce from the attack itself, any number of nervous complications may set in, all of which require special treatment.

Dr. W. Clarkson, of Montreal, Canada, remarks:

The treatment of this condition resolves itself into the management of: a, a syncopal form, heat exhaustion; b, an asphyxial type, insolation, or sunstroke proper; and c, a hyperpyrexial subtype of this latter, known as thermic fever.

Treatment is both prophylactic and active.

1. Prophylaxis.—This is of paramount importance. Temperance in eating and drinking are to be specially enjoined on those whose occupation predisposes to endure heat with physical exertion. The clothing must be loose and light, and the head well protected from the sun's says. Overfatigue is to be guarded against, and frequent bathing in hot weather is an excellent preventative measure.

2. Active treatment.—A. Heat exhaustion: In a mild case put the patient to bed between warmed blankets, hot water bottles being placed near the trunk and extremities. If stimulation is indicated use aromatic spirit of ammonia in drachm doses, hourly repeated in hot lemonade, only resorting to the hypodermatic use of strychnine sulphate, gr. I/20, in severer cases. If temperature is subnormal, an efficient restorative will be found in a general hot mustard bath, repeated in two or three hours, as necessary.

B. Sunstroke proper: Speedy antipyresis is the primary indication here, and cold hydrotherapy is our sheet anchor. The ordinary measures called for in a very mild case—to loosen all constricting clothing, lay patient on back in a cool, shady place, and dash cold water over face and chest, with, perhaps, the employment of some rapidly diffusible stimulant if the depression continues.

More energetic measures are demanded in a severe case: a cold bath is employed, the patient is put into a bath, temperature of 80° F., and ice gradually added until temperature reaches 60° F.; meanwhile the patient is being rubbed with ice; immersion is continued until rectal temperature is found to register 101° F., when the bath is discontinued, as the temperature will continue to fall for some time. Should a secondary rise of temperature occur, we employ the cold sheet pack for moderate rises, or another ice bath for a severe after fever. Free stimulation by means of whiskey, ½ ounce, or strychnine sulphate. 1-20 grain, hypodermatically as required—should be given if collapse symptoms supervene.

toms supervene.

C. Thermic fever: Here even a more immediate reduction of the temperature than in the case of sunstroke proper is demanded. Claudius's method, modified to meet individual cases, will be found

highly satisfactory. The patient is stripped, a thermometer inserted in the rectum, the body enveloped in a sheet, and laid on a stretcher; pieces of ice are packed around the body and larger blocks about the head; now a fine stream of iced water is allowed to trickle upon the forehead for a minute or two at a time. This will be of invaluable assistance in resuscitation. Discontinue all these measures when rectal temperature registers 103° F. While applying these measures, it is customary to give digitalin, 1/15 of a grain hypodermatically, except in cases of plethora, when venesection is indicated, followed by small repeated doses of digitalin. Otherwise, treatment is identical with that of sunstroke proper.

Special measures: After all pronounced symptoms have subsided, treatment is symptomatic, special symptoms demanding special treatment.

Conclusions: Chloroform inhalations are useful, and may be supplemented by hypodermatic injections of morphine sulphate and atropin. Hot baths are of service.

Heart Failure: Digitalin, strychnine sulphate, or camphor in olive oil is indicated in full therapeutic doses.

Asphyxia: Venesection is indicated, followed by saline transfusion. Artificial respiration is of service in cases threatened with respiratory paralysis.

vice in cases threatened with respiratory paralysis. After treatment: Light dietary and fresh air, with a possible prolonged sojourn in a cool climate, will be productive of much benefit.

Dr. Samuel L. Salasin, of Philadelphia, Pa., says: says:

Sunstroke, or, more correctly speaking, heatstroke is divided into two distinct classes.

One is that in which the excessive exposure to heat upsets the thermal mechanism of the body so that fever results, thermic fever; and the other in which the temperature of the body is lowered, which is known as heat exhaustion. These conditions must be treated according to the dangers in which the persons affected are placed.

The danger of thermic fever is that the high temperature may cause coagulation of the myosin in the heart muscle and of the protoplasm in the brain.

The danger of heat exhaustion is death due to collapse caused by general failure of the functions of the vital organs and the chilling of the body.

The treatment of these conditions is therefore entirely different. In treating a case of thermic fever, the first thing to do is to loosen the clothing and, if possible, remove it. If the pulse is full and bounding, and the patient is cyanotic, freely bleed him. At the same time cold applications should be applied, especially to the abdomen, back, chest, and head. While doing this the body should be thoroughly and briskly rubbed so as to bring the hot blood to the cold parts. Rectal injections of ice water have proved very beneficial.

A thermometer in the mouth or the rectum of the patient should be carefully watched so that there should not be a too sudden drop of temperature followed by collapse. When the temperature is reduced to about 101° F., the cold applications should be stopped, the patient dried, placed on a cot, and

covered lightly. An ice cap should be placed on the head and small pieces of ice should be given to the patient to swallow so as to allay the gastric irritability. The temperature should be watched, because in a few minutes there is a liability of its rising again, which would require further applications of cold. This second rise is due either to a disorder of the heat producing centre or to the fact that while the surface of the body is cool, the blood in the internal viscera is still at a high temperature, and rapidly heats the surface as soon as the ice is taken away.

If free sweating does not occur after the reduction of most of the fever, a hot bath and a hypodermatic injection of pilocarpus should be given. The patient should then be carefully watched for three or four days, as he is in danger of a simple meningitis. For several days, the diet should be

In heat exhaustion, the bodily temperature should be raised by means of heat and stimulation. The head should be lowered if possible. Hot baths at a temperature of 110° F., hot bricks, and rectal injections of hot water should be used. In cases where the external temperature is below normal and the internal temperature is found to be high, the rectal injections should be cold instead of hot. For stimulation, hypodermatic injections of strychnine, atropine, camphor, brandy, or ether should be used.

By the mouth, aromatic spirits of ammonia should be given. To combat the nervomuscular weakness, strychnine and digitalis should be used for a day or two.

Dr. Frank E. McCann, of Louisville, Ky., observes.

The chief danger from sunstroke, or, more properly, heatstroke, consists in the superheated condition of the body, which leads to carbonization of the blood and to paralysis of the heart through its effect on the heat centres of the brain.

As this is the chief danger so is it the physician's chief duty to relieve this hyperpyrexia as quickly as possible. Immediately on reaching the stricken person apply ice and ice water to the head, then remove the clothing, or at least a good portion of it, and place the patient in a bath of ice water, the surface of the body being rubbed vigorously all the while. If a bath is not convenient, the surface of the body may be rubbed with pieces of ice and cold water poured over it.

Combined with this, ice water enemas are very efficacious in reducing the temperature, which should be closely watched, and when down as low as 99° or 100° F., the patient should be placed in dry blankets, and if the pulse is rapid and weak, an injection of normal saline solution should be given subcutaneously or better still intravenously in the arm. If the heart still flags resort may be had to clixir digitalin by hypodermatic injection.

If reaction fails to set in and the temperature again rises the patient should be again placed in the ice water as before, and the treatment kept up until the temperature again falls. This should be repeated as often as the temperature rises, until it finally remains near normal.

If convulsions follow cucuas of chloral or inhala-

tions of chloroform may be given. The patient must be kept at absolute rest and quiet for a number of days.

Dr. Joseph Baum, of New York, writes:

As in cases of drowning, attention to those who are sunstruck must be immediate and purposeful. At once remove the patient to the nearest shady location; cut his clothes from him, exposing his body to the air; cold water, or better a piece of ice or an icebag, should be applied over the entire cranium; an ice cloth or ice bag or lump of ice should be placed over the præcordium; sprinkle the body with cool water, and then rub the surface of the body with a piece of ice (in a cloth); all this is to aid the radiation of heat from the unfortunate's body.

Do not allow any one to pour whiskey or other stimulant down the throat; do not hold strong ammonia to the nostrils; do not pump hypodermatic injections of strychnine into the unresisting body; a wildly pulsating heart, already overstimulated, does not need to be whipped further, it needs to be soothed and quieted, it needs regulation. And right here is where the old fashioned, almost obsolete, method of blood letting serves a useful purpose. for by removing twelve to fifteen ounces of blood from the general circulation, we use the most scientific and logical means of restoring the tumultuous heart action to something like a normal state.

To sum up, immediate resourceful treatment at the place where the casualty occurs; assisting the radiation of heat from the body by local cold or a general cool bath; the withdrawal of fifteen ounces of blood from the circulation; the avoidance of hypodermatic stimulation by cardiac stimulants; and then to the hospital for further observation will save many a case.

Dr. C. D. Martinetti, of Orange, N. J., says

Prolonged exposure to heat, especially in a moist atmosphere, very frequently results in an affection in which two grades may be distinguished.

The common mild form of heat prostration under which come most of the cases reported every summer by the daily papers shows more or less pronounced exhaustion, weakness, faintness, and nausea. Sometimes are added pallor, depression, collapse, and coma with subnormal temperature as low as 95° F. These patients, even if left to themselves, usually recover in a few hours.

The real sunstroke or heatstroke, however, has an abrupt onset, being rarely preceded by dizziness and faintness. The patient becomes flushed and unconscious, with profuse sweating, delirium, vomiting, and very high temperature. Unless assistance is forthcoming death rapidly follows from cerebral anæmia or cessation of respiration. A hot, moist atmosphere is uniformly fatal, especially when a person is predisposed by alcoholic or other excesses or previous ill health.

When called to a simple case of heat prostration our efforts must be directed immediately towards elevating the temperature of the body by the application of external heat, hot bath, hot drinks, alcohol, friction and stimulants.

A hypodermatic injection of strychnine nitrate,

1-30 grain, is most beneficial, to be repeated if necessary in half an hour.

In the real sunstroke, instead, our every effort must be directed towards reducing the temperature. A 10 grain dose of acetphenetidin or antipyrine should be at once administered either by mouth or hypodermatically. Ice water is a necessity, the patient being kept sprinkled with it until his temperature falls to about 101° F.

Then he is wrapped in blankets and placed in bed. Convulsions may require ½ grain of morphine, or preferably a hypodermatic injection, composed of morphine sulphate, ¼ grain; hyoscine hydrobromate, 1-100 grain. In any and every case of heat stroke, whether mild or severe, once the more severe symptoms have been attended to, 1-10 grain of calomel should be given every fifteen minutes until one grain is taken.

Patients suffering from heat stroke rarely recover promptly, and completely. Headache usually follows, also deafness, impaired memory, paralysis, or meningitis, besides functional irregularities of heart action.

Heat stroke may to a great extent be prevented by those exposed wearing suitably light clothing, avoiding stimulants, drinking large quantities of water, and paying proper attention to the evacuation of the bowel.

Dr. L. A. Crutcher, of Louisville, Ky,. remarks:

In treating sunstroke I have the patient placed in a quiet, well ventilated room, and at once I loosen the clothes. Then begin to reduce the temperature by the use of cold baths or cold pack, etc. I also use a hypodermatic injection of quinine or atropine; then the patient must be wrapped in a wet sheet, this tending to prevent subsequent rising of temperature.

When the patient is restless or convulsive, morphine, ¼ grain, hypodermatically is given, and if the pulse is feeble, stimulants of strychnine, nitroglycerin, or digitalis may be given.

This line of treatment, in all of my experience, has proved to be very successful.

Dr. J. Lytle Moore, of Toledo, Ohio, states:

Osler recognizes two conditions caused by excessive heat, viz.: heat exhaustion and sunstroke or insolation. In the former, following a prolonged exposure to the sun's rays or high temperature, there are extreme prostration and subnormal temperature. In sunstroke there are very high tem perature, unconsciousness, and frequently convulsions. I will consider the treatment of both conditions in this article.

Ætiology. Before mentioning the treatment, it will be well to look into some of the underlying causes. The active cause is prolonged exposure to the sun's rays. Unsuitable clothing and lack of protection to the head and spine are other prolific causes. Alcoholism, violent exercise, excess of proteid food, insufficient sleep, improper hygiene, constipation; and, in fact, anything which lowers the body resistance will act as a predisposing cause. Those who have had one attack are more susceptible to the sun's rays, and so more liable to sunstroke.

Sunstroke is frequently met with in the army, when soldiers are taking long marches; and it is also more common among the laboring class of peo-

ple, especially those who use alcohol.

Prophylaxis. So we see from the ætiology, the prophylactic treatment is to avoid anything which tends to bring the body resistance below par. Those working in the sun should wear suitable clothing and use protection to their heads. Prolonged exposure to the sun, and violent exercise on a hot day should be advised against. And, finally, those who have had an attack of sunstroke should take the greatest precaution when exposing themselves on a hot day.

Treatment. If the attack occurs upon the street or in a field, the patient should immediately be taken to a cool, shady place, where there is plenty of fresh air. Absolute rest is a very important point in the treatment of sunstroke. Remove all unnecessary clothing. If needed, give stimulants—a hypodermatic injection of strychnine or ether, or whiskey, or let the patient cautiously inhale the fumes

from a bottle of ammonia.

After doing this, the treatment is mainly symptomatic. One writer has made the statement that cold water, stimulation to the heart, and unloading the bowels are all the treatment needed in most

cases of sunstroke

The hyperpyrexia should be met with by the application of cold. Apply ice to the head and spine. If ice is not at hand, use cloths wrung out of cold water, and change them as soon as warm. Another good way is to place the patient in a tub of cold water. If this cannot be done, wring a sheet out of cold water and wrap it around the patient, and sprinkle cold water upon it now and then. Another very useful means of using cold is by the cold douche to the head and spine. This should only be used for a few minutes at a time. It reduces the temperature and also stimulates respiration. In severe cases give also an enema of ice water.

This cold water treatment should be used persistently until the temperature comes down to 100° F. Then put the patient to bed, covered up with blankets, place hot water bottles to the feet, and use stimulants as are indicated. The best ones are ether, strychnine, camphor, and whiskey. A hypodemaclysis of one to two pints of normal salt solu-

tion is one of our best means.

A purgative enema and a brisk cathartic should be given in all cases. Diaphoresis should be encouraged by warm sponging and the use of Warburg's tincture. Also watch the kidneys to see that they are functionating properly. The object of these measures is to eliminate all toxic substances from the body. A mustard paste applied to the neck is a favorite therapeutic measure.

When convulsions are present, control them with a few drops of chloroform and a lukewarm bath. Also give hypodermatically, ½ to ½ grain of morphine, guarded by 1-150 grain of atropine.

For the restlessness and insomnia give a warm sponge bath. If this does not produce the desired effect, give bromides. The persistent headache should be treated with coal tar products, salicylates, a bromides, and the patient kept quiet.

Man physicians peak very highly of bleeding

in the treatment of sunstroke. The only instance where I think it is justifiable is in those cases which present cyanosis and dyspnæa, in a plethoric person.

When the temperature is subnormal and there is great prostration, as in heat exhaustion, put the patient in a hot bath, then cover him well in bed, with hot water bottles around him. Stimulate freely. A hypodermoclysis is one of the best means in these cases.

The convalescence should be treated symptomatically. Tonics and plenty of nourishment are indicated. The patient should live a quiet life, and should avoid all unnecessary exposure to the sun on a warm day. His occupation should be one which does not require much exertion or mental concentration. He should be a rigid observer of the laws of hygiene. The physician should advise him to spend his summers in a colder climate. By these means he can be comparatively free from the unpleasant after effects of sunstroke.

Therapentical Hotes.

The Iodine Treatment of Typhoid Fever.—In the Journal de médecine de Bordeaux, for June 7, 1908, Dr. J. P. Lafitte, of Santiago, Chile, gives the composition of the compound solution of iodine which he uses hypodermatically in the treatment of typhoid fever. It is as follows:

(The quantities of the different ingredients should be taken by weight.)

Inhalation for Whooping Cough.—The following is recommended to be added, a tablespoonful at a time, to a bowlful of boiling water, kept in proximity to the patient:

13 Naphthalene, Six,
Camphor, Si
Oil of eucalyptus.
Oil of pine needle, ãã q. s.

[It is to be presumed that enough of the oils are taken to effect dissolution of the naphthalene and camphor.]

For Dysenteric Diarrhea,—The following is prescribed by Pouchet (Journal de médecine de Paris, May 30, 1908):

1: Bi muth saleylate. 5ui;
Camphorated tincture of opium, 3iv;
Glycerin. 5us;
Peppermut water. 5w.
M. et sig: Tablespoonful every hour.

Combined Method of Treatment for Tuberculous Lesions of the Face (Lupus Vulgaris, Etc.)—J. Goodwin Tomkinson (The Practitioner, June, 1908) employs the following combined method of treatment of cutaneous tuberculosis (lupus vulgarus and tuberculosis verrucosa): If any crusts exist they are removed by the application of a salicylated ointment. A tentative x ray exposure of from three to five minutes is made upon a small area of the lesion. In a few days the x rays are directed

for about five minutes daily upon a somewhat wider area of the lesion, unless contraindicated, until the whole lesion has been exposed some three or four times. It is then plastered with Unna's fifty per cent. salicylic acid and creosote plastermull, which is renewed daily. If its application is badly borne, the part is previously swabbed with ten to twenty per cent. solution of cocaine. In a variable number of days—approximately about ten and determined by the individual case—it is found that much of the tuberculous tissue has come away. The lesion is then swabbed with cocaine solution, then dried, and afterwards painted with the following preparation:

A few minutes afterwards the lesion is painted with the following solution:

B Carbolic acid, Us lxxx;
Absolute alcohol, Us lxxx

After cauterization the part is dressed for a day or two with sterilized lint and carbolated oil (I in 30), and, thereafter, with twenty per cent. aqueous solution of ichthyol, until healing has taken place. After healing x ray treatment is recommended, short exposures of three to five minutes—rarely longer—being made. At the end of three or four months the treatment is discontinued for a considerable time, during which the patient returns periodically for inspection.

Treatment of Chronic Intestinal Catarrh.— Von Aldor (Berliner klinische Wochenschrift, April 13, 1908; Journal de médecine de Paris, May 30, 1908) advises the use of the following prescription for the treatment of the symptoms of chronic catarrh of the intestines:

| $\mathbf{P}_{\!\scriptscriptstyle{E}}$ | Bismuth subnitrate, |
|--|---------------------|
| | Bismuth naphtholate |
| | Calcium phosphate, |
| | Calcium carbonate, |
| | Resorcin,gr. viiss |
| 3.1 | |

Sig.: Take as much as may be lifted on a dime every three hours.

A laxative should be prescribed every four or five days.

The Treatment of Obesity.—In the Journal de médecine de Paris, for May 30, 1908, W. Mladejorsky is credited with the following combination in pill form for the reduction of obesity:

| B | Thyreoid extract, |
|----|---|
| | Sodium and theobromine salicylate,āā gr. x; |
| | Podophyllin,gr. ss; |
| | Quinine hydrochloride,gr. v; |
| | Extract of cascara sagrada,gr. ii: |
| M. | ft. pil. No. xii. |

Sig.: Take six to nine pills every morning on an empty

Some Active Principles of Digitalis.—The most active principle of digitalis is digitoxin, though its activity does not represent more than one fourth of the total power of digitalis leaf. It is practically identical with *Digitaline crystallisée* (Nativelle), and the dose is the same—namely, I/250 to I/60 grain. *Digitalin* (German) consists of a mixture of

glucosides, and is much less active. Dose, 1/60 to 1/30 grain.

The Treatment of Pruritus Ani.—After fomenting the parts with hot boric acid or phenol solutions of appropriate strength, it is recommended in Memento therapeutiques des praticiens (Le Monde médical) to apply the following ointment:

| P_k | Oil of peppermint, | gtt. | xv; |
|-------|--------------------|-----------|------|
| | | gr. x | dv; |
| | Soft petrolatum, | | |
| M. | Olive oil, | āā | ÚSS, |
| | | | |

Following the application of the ointment a suppository should be used, the following being suggested:

| P, | Oil of theobroma,gr. xlv; | |
|----|--|--|
| | Morphine hydrochloride,āā gr. 1/3 to gr. 3/4 | |
| М. | ft. suppositorium No. i. | |
| | | |

| M. | contract for | | | | | | |
|--------------|--------------|-----------|--------|------|------|-----|------|
| r be | tter: | | | | | | |
| \mathbb{R} | Cocaine | hydrochi | oride, | | | gr. | xxx; |
| | | subnitra | | | | | |
| | Soft pe | trolatum, | | | | | 3x. |

In order to rid the tract of worms calomel may be given in combination with santonin, 1/6 of a grain of santonin being taken for each year of age.

If hæmorrhoids are present either one of the following ointments may be applied night and morning:

| \mathbf{R} | Carbolic acid,gr. viiss, |
|--------------|--|
| | Ergotin, |
| | Extract of hamamelis, |
| | Tincture of benzoin, |
| | Wool fat. |
| | Soft petrolatum,āā 3v |
| M. | por por ording reserved to the port of the |
| 212. | II. |
| \mathbf{R} | Iodoform |
| | Extract hamamelis. |
| | Extract namamens, |
| | Extract of hydrastis, |
| | Zinc oxide,3v |
| | Lime water, |
| 3.5 | Linseed oil, |
| | |

The objectionable odor of the iodoform contained in the last formula makes the ointment difficult of application in some instances, and if necessary the iodoform may be replaced by salol.

In simple pruritus the application of a 1 in 40 solution of menthol in alcohol as a paint will be found useful.

Equally serviceable is the topical application of an ointment made as follows:

| P _i | Liniment | of lime | water, | , . | | | , |
|----------------|----------|---------|--------|-----|------|------|----|
| 11 | Carbolic | acid, | | | | | î. |

Hypodermatic Injection for Hepatic Colic.— The following solution is employed in appropriate dosage hypodermatically for the relief of hepatic colic:

| \mathbf{R} | Morphine hydrochloride,gr. iss |
|--------------|--------------------------------|
| | Distilled water, xxx |
| | Alcohol (90 per cent.), |
| 1.0 | Ether, |

NEW YORK MEDICAL JOURNAL

SUBSCRIPTION PRICE

Under Domestic Postage Rates \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, JULY 11, 1908.

THE DEFECTS OF THE NEW YORK AMBULANCE SERVICE.

The ambulance wagons maintained by the hospitals of New York perform a service which can hardly be overrated, but its very excellence makes us wish all the more that it was perfect, and perfection really seems attainable. For its improvement, however, it is necessary that attention should be drawn to its shortcomings. This has recently been done by one of the committees of the State Charities Aid Association on the basis of a report by Mr. Phil P. Jacobs, who was employed by the committee to present a picture of the present conditions.

Each hospital which operates one or more ambulance wagons has assigned to it a district which it is depended on to cover and beyond the limits of which it is not supposed to extend its activities, but it is not a very uncommon occurrence for two or more wagons from different hospitals to meet at the scene of an accident. It has happened, indeed, that the surgeon of one hospital, finding himself not to be the first to arrive, has in all courtesy ordered his wagon to return without the patient, and the other surgeon has then found the case unsuitable for treatment in the hospital represented by him, whereupon he, too, has left the sufferer to go without hospital assistance. Such an event comes about by reason of two citizens having summoned relief from two different hospitals, and the calls being complicated by somebody's ignoring the district boundaries.

In other instances, again, no wagon at all is forthcoming or one arrives only after an inordinate delay. This is sometimes due to the fact that the call was sent by some sympathetic citizen who, in innocent disregard of established routine and in his haste to secure aid for an unfortunate person, has acted himself instead of finding a policeman to do it, for it seems that there is a general understanding among the hospitals that an ambulance call received in any other way than through the police force is negligible, although the police are not legally charged with the sole authority to send a summons. In many instances delay is due to the fact that the hospital properly appealed to has already sent its wagons to the scenes of other accidents, far away, so far that their return is exceedingly tardy. This unfortunate occurrence is apt to be due to an awkward arrangement of the districts whereby the hospital to which a district has been assigned is situated, not centrally, but close to one of the boundaries of an extensive area.

The chief recommendations made are that there should be established a bureau of ambulance service, and that calls should be receivable only by the officer in charge of the bureau, who, unless he has good reason to think that a call is unnecessary, shall direct the proper hospital to respond. In case any private hospital fails to comply with the requirements, the city shall itself conduct the ambulance service in the district which would naturally belong to that hospital. It is proposed that the bureau be under the control of the Board of Trustees of Bellevue and the Allied Hospitals, and that the division of the city into ambulance districts be revised. These recommendations seem reasonable and easy to carry

DIET AND ENZYME ADAPTATION.

That an intimate relation between the chemical receptors of the gastrointestinal tract and appropriate nervous correlation exists is beginning to be appreciated, and it seems not improbable that there are a great number of such chemical stimulus receptors which are, perhaps, just as specific in their reactions as the external receptors are to heat, cold. light, and sound stimuli. We must remain for the time in the fact gathering period of this work: it would be premature to generalize now. Of recent observations in this sphere, the study of C. H. Neilson and D. H. Lewis, from the Physiological Department of St. Louis University, on The Effect of Diet on the Amyolytic Power of Saliva (Journal of Biological Chemistry, June), is especially instructive from this general point of view.

Neils n and ferry, in 1900 showed that when

dogs were kept on a carbohydrate diet the saliva which was secreted was richer in amylolytic power than when the dogs were on a meat diet. These results have been contradicted by other observers; hence the authors have thought to determine just what effects a carbohydrated diet might have on human saliva. Simon, in 1907, reported that a carbohydrate diet caused an increase in amylolytic ferments in the saliva, and the extensive study here outlined by Neilson and Lewis goes to establish this view, in spite of the contradictions of other observers.

The authors are at a loss to explain this change, but it is not difficult to conceive of a specific enteroreceptor, to use the language of Sherrington, that responds to carbohydrates and, producing the proper stimulus, results in the correct adaptation on the part of the nervous mechanism of the salivary glands to secrete the appropriate ferment. It is true we are, as yet, but groping in the dark. The receptive lining of the gastrointestinal tract responds almost exclusively to chemical stimuli, and, although it is thought that these internal digestive organs are sparsely endowed with receptive organs, when compared with the free enteroreceptive surface outside, such may be far from being the case. Should the present conclusions stand, they would point in the direction of specific carbohydrate receptors quite analogous to others with which we are already familiar.

TUBERCLE BACILLI IN THE FÆCES.

In many textbooks on clinical pathology the statement is made that the occurrence of tubercle bacilli in the fæces is indicative of intestinal ulceration, or that it is the result of the swallowing of tuberculous sputum. It has been shown by a number of observers, however, that bacilli may be passed from the blood into the lumen of the intestine, and vice versa through an intact mucous membrane. The studies of Rosenberger (Proceedings of the Pathological Society of Philadelphia, February) show that the bacillus may be found in the fæces when there is no pulmonary lesion from which the patient might swallow sputum and when there is no intestinal lesion; in cases of general glandular involvement. meningitis, hip joint disease, etc.

Following the demonstration of acid fast bacilli in the fæces of patients with symptoms which did not admit of a positive diagnosis, Rosenberger undertook the examinations of the fæces of 672 patients in the Philadelphia General Hospital for the presence of such organisms. The technique is quite simple: A small piece of the material is smeared on a slide, being emulsified with water if it is solid or semi-

solid, dried in the air, and fixed in the usual manner. The preparation is then stained with cold carbol-fuchsin for twenty minutes; after draining off the excess, Pappenheim's solution is applied for two minutes, and then the preparation is washed with water. If the specimen is not of a uniform blue color, Pappenheim's solution is again applied for one minute, and the preparation is washed anew. This process is continued until the specimen is uniformly blue. The film is then dried and examined with a twelfth inch oil immersion lens. By this method the tubercle bacillus was found in the fæces in all the tuberculous patients, and in 120, 19.6 per cent., of the 612 patients who did not present positive clinical evidences of tuberculous disease.

Rosenberger concludes that no other acid fast bacillus is found in the fæces than the tubercle bacillus. The presence of these organisms in the fæces means that an active tuberculous process exists somewhere in the body. In the acute miliary form the bacilli are always present in the fæces, and their occurrence there does not always indicate intestinal ulceration. The author advises that the fæces be examined for tubercle bacilli in all cases of chronic diarrhæa and general glandular involvement, and in all cases in which pulmonary tuberculous disease is suspected, but in which no sputum can be obtained for examination.

In the discussion which took place at the meeting at which Dr. Rosenberger read his paper, several objections were raised to some of his conclusions. We know of more than one laboratory, in which the method has been adopted, in which the results have not been so satisfactory as those reported in the paper under discussion. However, Rosenberger spent as long as two hours in searching for the organisms in some of his specimens before he found them, or before he arrived at the conclusion that they were absent. It is possible that lack of patience is one reason why others have failed to obtain the same results as those recorded in the paper. The objection raised by one member, that the bacilli had been found in the person of a perfectly healthy individual, is not so easy to answer. The method is simple, and there are many reasons why others should endeavor to confirm or refute the conclusions of the author.

THE EXCRETA OF TUBERCULOUS CATTLE.

The question of the dissemination of tuberculous disease by the excreta of tuberculous cattle, particularly by their fæces, has been investigated anew by Dr. M. H. Reynolds, the veterinarian of the Agricultural Experiment Station of the University of

MIDICAL TOLKS VI

Minnesota, and Dr. W. L. Beebe, the bacteriologist of the Minnesota Live Stock Sanitary Board, and an account of their work is presented in *Bulletin No. 103* of the Veterinary Division of the station. They cite previous similar investigations by Schroeder and Mohler and Schroeder and Cotton, of the Bureau of Animal Industry, with whose findings their own do not wholly coincide.

Schroeder and Cotton concluded that cows rarely if ever passed tubercle bacilli in the urine unless the genital or the urinary organs were involved in tuberculous disease; also their results with the nasal secretion, both on microscopical examination and by inoculation tests, were negative. Those observers found, however, that virulent bacilli were usually passed in the fæces, uniformly distributed through them, by cows that responded to the tuberculin test, and they estimated that ordinarily such a cow would give off daily 37,800,000 bacilli demonstrable with the microscope, and several times that number not thus demonstrable. They are convinced that there is no more fruitful manner of dissemination of tuberculous disease from cattle than by their virulent fæces-to other cattle confined in stables and to man by the contamination of the cows' milk with their dried fæces, provided no more than ordinary cleanliness is observed by the milkers.

Reynolds and Beebe, on the other hand, were not able to satisfy themselves that more than one tuberculous cow out of the forty-five with which they experimented was passing virulent tubercle bacilli with the faces, and their inoculation tests with the nasal secretion of fourteen tuberculous cows were barren of results in all save two inoculations from one of the cows, and that one cow was the only one whose faces were shown to be virulent. On post mortem examination, that particular cow was found to have had tuberculous disease of various structures, but no ulcers of the intestinal mucosa were found, though the entire intestine was very carefully examined. Both lungs contained many abscesses, and both retropharyngeal lymph glands showed caseous areas.

In the most catholic spirit, the Minnesota observers, far from questioning others' findings, simply indicate the need of further investigations. They remark that, if a considerable proportion of tuberculous cattle are passing virulent bacilli in the fæces, the amount of dissemination thus made possible is serious both for other cattle and for human beings; and, if but few such cattle are passing virulent bacilli, "those few are dangerous and seriously objectionable factors in any herd." They add: "Until further information is available, and considering the disastrous results which have been shown to be possible from virulent manure, it becomes evident that

tuberculin reacting cattle should not be allowed to remain in any stable from which milk is taken for food purposes or where they are associated with healthy cattle, even though the milk of the reacting cows be discarded."

TUBERCULIN IN DIAGNOSIS AND TREATMENT.

To the best of our knowledge, this journal was the first to suggest caution and to express misgivings at the time of the initial furore of enthusiasm consequent on Koch's original announcement of the probable therapeutic value of tuberculin (see the New York Medical Journal for November 22, 1890, page 570). It was not long before optimistic expectation gave place to acknowledged disappointment, and at length tuberculin fell into almost complete disuse as a therapeutic agent. Of late, however, there have been some signs of a partial revival of confidence in tuberculin, and perhaps it is this fact that has prompted an eminent member of the New York profession to seek for a consensus in regard to the matter.

Specifically, he asks the following questions, all bearing on the use of tuberculin for diagnostic purposes: 1. Should tuberculin injections be employed as a routine measure? 2. Are these injections reliable and positive in all cases and stages of tuberculous pulmonary disease? 3. Are they absolutely free from danger? 4. Do they ever awaken a latent tuberculosis? 5. Would you employ them in a case of suspected tuberculosis in a member of your own family? In accordance with the gentleman's request, we hereby invite clinical observers-"leading lights in phthisiólogy," the gentleman himself phrases it-to answer the questions. Perhaps few will care to answer them by yes or no without qualification; were we obliged to do so, we should answer the fourth question in the affirmative and all the others in the negative. We think that most careful observers will agree with Dr. James M. French, formerly lecturer on the theory and practice of medicine in the Medical College of Ohio (Textbook of the Practice of Medicine, third edition, New York, 1907, page 386), when he says:

This method of diagnosis is still employed by some physicians who regard it as both safe and sure, but a majority condemn it. There can be no doubt that in many instances its use lights up a latent process; the slight fever of reaction is continued into a fever of tuberculization, and the diagnosis is confirmed at the expense of awakening a sufficient demonstration, in most cases, of the existence of tuberculosis somewhere in the body, but the test should be employed with the utmost care, as a rule only when it is made advisable by special circumstances, and in full understanding of its dangers. It is highly probable, however.

that many of the reported unfavorable results have arisen from the use of too large and too frequent doses.

Concerning the therapeutic use of tuberculin Dr. French says (page 398):

The treatment with tuberculin has been almost entirely abandoned everywhere, on account of unfortunate results which were repeatedly observed after its administration. The new tuberculin (T R) has been found even more dangerous than the original. Employed in suitable cases, not too far advanced, and never when fever is present, it has been found of decided benefit and often curative in the hands of competent observers, notably Wright, of London, who first renders it sterile by heat and carefully regulates its administration by the opsonic index of the patient.

Calmette's device, that of dropping a weak solution of tuberculin into the conjunctival sac, may have some advantages, but it must not be forgotten that serious disease of the eye has been occasioned by it, not, however, eventually destructive, it is affirmed. As for the still newer application by inunction, the data are as yet far too few to furnish material for any general statement of opinion.

Rems Items.

New York University has conferred the degree of Doctor of Medicine on 12,786 graduates during the last three quarters of a century.

The Medical Department of the University of Louisville held its annual commencement on June 30th. The degree of Doctor of Medicine was conferred upon ninetynine graduates.

The Royal Sanitary Institute.-The twenty-fourth annual meeting of this organization will be held in Cardiff Wales, on July 13th to 18th, under the presidency of the Earl of Plymouth.

The Society of Physicians of Canandaigua, N. Y., held a meeting on the evening of June 11th. The principal feature of the programme was a paper by Dr. F. E. McClellan on Anæsthetics.

Examination of Food and Drugs in New Jersey .--During the month ending June 30, 1908, there were examined by the New Jersey State Laboratory of Hygiene 651 samples of food and drugs, of which 585 were found to be above the standard and 66 below.

A Chinese Hospital in Chicago.—It is reported that the Chinese merchants of Chicago have made plans for the establishment of a Chinese hospital in Chicago. The institu-tion will be equipped with all modern appliances and will have a complete staff of physicians and nurses. It will probably be located in the heart of the Chinatown district.

Donation to the Red Cross Hospital at San Mateo, Cal.—Mrs. Whitelaw Reid, wife of the American Ambassador to the Court of St. James, has placed the sum of \$10,000 at the disposal of the directors of this hospital, to be used in building an annex to the hospital. This hospital, which was built last year, was organized by Mrs.

Union County, N. J., Medical Society.—The regular monthly meeting of this society was held in Elizabeth on Wednesday afternoon, July 8th. The principal feature of Wednesday afternoon, July 8th. The principal feature of the programme was a paper by Dr. Charles Gilmore Ker-ley, of New York, entitled The Intestinal Disorders of Children in Summer. The discussion was opened by Dr. Henry L. Coit, of Newark.

The Mortality of Chicago.—During the week ending June 27, 1908, there were reported to the Department of Health of the City of Chicago 508 deaths from all causes, as compared with 455 for the previous week and 479 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.23. The principal causes of

death were: Apoplexy, 16; Bright's disease, 35; bronchitis, death were: Apoptexy, to, Bright s disease, 35, bronchistor, 6; consumption, 47; cancer, 25; convulsions, 3; diphtheria, 12; heart diseases, 38; intestinal diseases, acute, 41; measles, 7; nervous diseases, 17; pneumonia, 41; scarlet fever, 3; suicide, 14; typhoid fever, 7; violence (other than suicide), 41; whooping cough, 6; sunstroke, 14; all other causes, 135.

Contagious Diseases in Chicago.—During the week ending June 27, 1908, the following cases of communicable diseases were reported to the Department of Health: Measles, 177 cases; diphtheria, 71 cases; scarlet fever, 44 cases; whooping cough, 36 cases; tuberculosis, 26 cases; chicken pox, 22 cases; typhoid fever, 12 cases; smallpox, 2 cases; miscellaneous diseases of minor importance, 3 cases; total, 393 cases.

Indiana State Medical Association .- At the annual meeting of this association, which was held recently at French Lick Springs, the following officers were elected: President, Dr. George D. Kahlo, of French Lick Springs; hirst vice president, Dr. E. D. Freeman, of Osgood; recording secretary, Dr. F. C. Heath, of Indianapolis; treasurer, Dr. A. E. Bulson, of Eart Wayne. The part meeting will Dr. A. E. Bulson, of Fort Wayne. The next meeting will be held in Terre Haute, in October, 1909.

Two New Hospitals for Brooklyn.-Plans have been filed for two new hospitals for this borough, one to replace the Bradford Street Hospital in East New York, and the other to be located in Greenpoint. The new hospital in East New York will cost approximately \$250,000, and it is said will be, when completed, one of the finest hospitals owned by the city. The Greenpoint hospital will be an emergency hospital, and will occupy a private house.

American Hospital Association.-The tenth annual Canada, on September 22d, 23d, 24th, and 25th. The pre-liminary programme, which has just been received, in-cludes more than twenty papers on subjects relating to hospital management, and the meeting promises to be one of special interest and value. Among those who will present papers are Dr. James Alexander Miller and Dr. C. Irving Fisher, of New York, and Dr. D. L. Edsall, of Philadelphia.

A Day Camp for Consumptives in Buffalo.-This camp, which is situated on La Salle Avenue, near Main Street, was formally opened on July 1st, with appropriate ceremonies. The camp will accommodate thirty patients, who will be selected from the applicants at the dispensary of the Charity Organization Society. Dr. George J. Eckel will have charge of the camp, and a trained nurse will have supervision of the patients. It is said that there are 2,500 cases of tuberculosis in Buffalo, and an effort will be made to establish a municipal tuberculosis hospital in the near

The Health of Pittsburgh .- During the week ending June 27, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chicken pox, cases, o deaths; typhoid fever, 32 cases, 4 deaths; scarlet fever, 14 cases, 2 deaths; diphtheria, 4 cases, 1 death; measles, 96 cases, 6 deaths; whooping cough, 5 cases, o deaths; pulmonary tuberculosis, 19 cases, 11 deaths. The total deaths for the week numbered 156 in an estimated population of 565,000, corresponding to an annual death rate of 14.35 in 1.000 of population. The death rate for the month of January was 26.51 in 1.000 of population.

Charitable Bequests.—By the will of Thomas Cunningham, various institutions in New York, including St. Francis's Hospital. Little Sisters of the Poor, and St. Joseph's Home for Consumptives, each receive \$2,000.

By the will of John S. Cullen, St. Elizabeth's Hospital.

Watertown, Mass., receives \$300.

By the will of Maria Elizabeth Jones, the Free Hospital for Women in Brookline, Mass., the Industrial School for Crippled and Deformed Children in Boston, and the Children's Hospital in Boston, will each receive \$10,000; the

Home for Aged Couples in Boston, will each receive \$10,000; the Home for Aged Couples in Boston will receive \$5,000.

By the will of William Barr, St. Luke's Hospital, St. Louis, the St. Louis Children's Hospital, the Episcopal Orphans' Home, St. Louis, each receive \$10,000; the Protestant Orphans' Home, St. Mary's Infirmary, Bethesda Home, Memorial Home, Home of the Friendless and Blind Cirkl' Home, St. Louis, reals receive \$700,000,000, No. 10. Girls' Home, St Louis, each receive \$5,000: Orange, N. J., Memorial Hospital, The Record Ambulance, Maintenance Fund of Orange, and the Orange Orphan Asylum, each receive \$5,000.

The Wisconsin College of Physicians and Surgeons, Milwaukee, is to have a new free dispensary building and two new laboratories. The two new laboratories are to be for experimental physiology and pharmacology. The faculty of the college has also been enlarged, the following new instructors in the medical department having been ap pointed: Dr. B. F. Armstrong, lecturer on embryology and operative surgery; Dr. Walter T. McNaughton, assistant in pædiatric clinic; Dr. Simon M. Madison, instructor in surgery; and Dr. George F. Zaum, clinical lecturer on oph-thalmology and otology. It has been decided to raise the standard of admission to the college, to take effect in 1910.

Crusade for Clean Creameries in New Jersey.—The State Board of Health of New Jersey has taken steps to enforce the recently enacted law compelling owners of creameries throughout the State to keep their premises clean and thus insure pure and wholesome products. Following the receipt of complaints from New York and Philadelphia, circulars were issued to creamery men instructing them that the site of the creamery building must be dry. the surroundings completely sanitary, the entrance of flies barred by screens, all milk, cream, and butter properly iced, all utensils thoroughly sterilized every twenty-four hours, and the milk and cream conform to the standard of quality specified by the State law

The Lehigh Valley Medical Association.-The tenth annual summer meeting of this association was held at the Water Gap House, Delaware Water Gap, on Wednesday and Thursday, July 8th and 9th. On Wednesday evening Dr. E. L. Reed, of Philadelphia, delivered a lecture on Tuberculosis as Seen Under the Microscope and Its Treat-Tuberculosis as Seen Under the Microscope and its Treatment by Bacterial Products, which was illustrated by the projecting microscope. On Thursday morning, after the transaction of routine business, the president's address on Criminal Abortion was delivered by Dr. J. T. Howell, of Wilkes-Barre, Pa., and Dr. John G. Clark, professor of gynacology in the University of Pennsylvania, delivered an address on The Remote Effects of Abdominal Operations of the property of the prope tions, after which the annual dinner of the association was

A Movement for Raising the Standard of the Milk Supply.-The Bureau of Animal Industry of the Department of Agriculture is sending to householders throughout the country cards on which answers are requested to a number of questions relating to the milk supply. Among the questions are the following:

How many persons in your family. How many children under five years? How much milk do you consume daily. How much cream?

riow much cream?
What proportion used for drinking?
Why do you not use more milk?
Hase son ever examined the darve supplying you with milk or seen any report concerning it?

While the avowed object of the cards is merely the collection of data for the bureau, it is believed that better sanitary conditions and purer milk will be the result.

Infectious Diseases in New York:

He are indebted to the Bureau of Records of the De-partment of Health for the following statement of new cases and deaths reported for the two weeks ending July

| 1 Julie | Jun | Tune 27 | | | |

Vital Statistics of New Jersey .- During the month ending June 15, 1908, there were reported to the Bureau of from all causes, an increase of 26 over the previous month, to than the extremental period in 1907. Of the total number of deaths, 444 were of infants under one year of age, 199 of dildren between one and the year of age, and 768 of per on instruction and and over. There were the after from typhoid fever 123 from measless 18 from ... t fever 2t from absorping cough, it from diph there a from malarial fever 306 from pulmonary tuber

121 from cancer; 22 from cerebrospinal meningitis; 345 from diseases of the nervous system; 289 from diseases of the circulatory system; 152 from diseases of respiratory system (pneumonia and tuberculosis excepted); 218 from pneumonia; 225 from diseases of digestive system; 190 There were 42 suicides from Bright's disease.

Personal.—Dr. S. A. Knopf, of New York, has been made an honorary president of the Congrès des Médecins de Langue Française de l'Amérique du Nord, which will convene in the city of Quebec during the celebration of the three hundredth anniversary of the founding of that city, July 20th, 21st, and 22d.

Dr. Charles R. Van Hise, president of the University of Wisconsin, has had the degree of Doctor of Laws con-

ferred upon him by Harvard University

Yale University has conferred the degree of Doctor of Science upon Dr. Graham Lusk, professor of physiology in the University and Bellevue Hospital Medical College. Dr. George Dock, professor of the theory and practice of medicine at the University of Michigan, has accepted the chair of medicine at Tulane University, New Orleans. Dr. Dock will take up his programmed where the fell terms Dr. Dock will take up his new work when the fall term opens.

The Samuel D. Gross Prize.—This prize of \$1,500 is awarded every five years by the Philadelphia Academy of Surgery to the writer of the best original essay on some subject relating to surgical pathology or surgical practice, founded upon original investigations. Candidates for the prize must be American citizens. Each essay must not exceed one hundred and fifty pages, octavo, in length; must be written in English by a single author; must be typewritten unsigned, distinguished by a motto only, and accompanied by a sealed envelope bearing the same motto, containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The unsuccessful essays will be returned if claimed within a year. The right is reserved to make no award if tlie essays submitted are not considered worthy of the prize. Essays must be sent in on or before January 1910, to the Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 219 South Thirteenth Street, Philadelphia.

The Health of Philadelphia.-During the week ending June 20, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Malarial fever, I case, 0 deaths; typhoid fever, 45 cases, 4 deaths; scarlet fever, 44 cases, I death; chicken pox, 9 cases, 0 deaths; diphtheria, 50 cases, II deaths; measles, 206 cases. 6 deaths; whooping cough, 15 cases, 9 deaths; cerebrospinal meningitis, 2 cases, 0 deaths; pulmonary tuberculosis, 107 cases, 52 deaths; pneumonia, 21 cases, 32 deaths; erysipelas, 5 cases, I death; puerperal fever, I case, I death: mumps, 4 cases, 0 deaths; cancer, 20 cases, 25 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 5; diarrhœa and enteritis, under two years of age, 34; dysentery, I. The total deaths for the week numbered 403 in an estimated population of 1,532,738, corresponding to an annual death rate of 13.61 in 1,000 of population. The total infant mortality was 112; under one year of age, 84; between one and two years of age, 28. There were 52 still births, 27 males and 25 females.

The Southern Medical Association.—The annual meeting of this association will be held in Atlanta, Ga., on November 10th, 17th, and 12th. The officers of the organization are: President, Dr. B. L. Wyman, of Birmingham, Ala.; vice presidents, Dr. B. L. Wyman, of Birmingham, Ala.; Dr. H. M. Folkes, of Biloxi, Miss.; Dr. Frank Watson, of New Orleans, La.; Dr. G. R. Holden, of Jacksonville, Fla.; Dr. Raymond Wallace, of Chattanooga, Tenn.; Dr. A. L. Fowler, of Atlanta, Ga.; secretar; and treasurer, Dr. Oscar Dowling, of Shreveport, La.; councilors, Dr. D. F. Talley, of Birmingham, Ala.; Dr. Michael Floke, of Atlanta, Ga.; Dr. John M. McDearmid, of De Land, Fla.; Dr. W. W. Crawford, of Hattiesburg, Miss.; Dr. W. W. Butterworth, of New Orleans, La.; Dr. George W. Savage, of Nashville, Tenn. Officers of sections: Section in Medicine—Chairman, Dr. Seale Harris, of Mobile, Ala.; secretary, Dr. H. E. Mitchell of Birmingham, Ala. Section in Surgery—Chairman, Dr. W. F. Westmoreland, of Atlanta, Ga.; secretary, Dr. J. L. Crook, of Jackson Lenn. Section in Ophthalmology Chairman, Dr. J. F. Herron, of Jackson, Tenn.; secretary, Dr. A. B. Harris, of Birmingham, Ala The Southern Medical Association .- The annual

An Unusually Extensive Milk Borne Outbreak of Typhoid Fever, By Charles Harrington. A Glomerular Lesion of Experimental Nephritis, By Henry A. Christian. The Menace of the Swimming Tank, By Carollus M. Cobb. Alphamonobrom Isolvalerylurea. A New Nerve Sedative and Sommifacient. By William Henry Porter.

A Glomerular Lesion of Experimental Nephritis.—Christian has observed a glomerular lesion while studying some experimental renal lesions. The lesion consists of the appearance in the glomerular tuft of small, round or oval, rarely irregular, homogeneous droplets, varying from a half to four microns in diameter. These droplets appear in the wall of the capillaries making up the glomerular tuft, and do not occur either in the lumen of the capillaries or in the space between the glomerular tuft and the capsule of the glomerulus except in rare instances, when their position might be explained as an artifact in preparation. They were not found in the epithelium lining Bowman's capsule. In some glomeruli only a few scattered droplets occur, while in others they are very numerous. Very often in a glomerulus they tend to occur in groups of three to six or eight, and where the larger groups are found, almost always some of the droplets are considerably coarser than others of the same group. In some rabbits almost every glomerulus contains many droplets of fairly large size; in others the droplets are uniformly smaller. In some rabbits some glomeruli contain numerous droplets while adjacent glomeruli are free from them. This focal distribution seemed to have no relation to the other lesions of the kidney, and no cause for it was to be made out. In kidneys showing slight degrees of the lesion, only here and there a glomerulus showed a few fine droplets In a series of twentysix successive rabbits studied in this connection. these droplets were found in the glomeruli of thir-Thirteen of this group of animals teen animals. had received doses of uranium nitrate, and of these thirteen, eleven showed the lesion in a varying degree. The other two rabbits which showed this glomerular lesion were animals which had received doses of potassium bichromate. There were four such animals, and two of these showed the lesion slightly marked. The animals failing to show the lesion had been treated as follows: One rabbit had received both potassium bichromate and mercuric chloride, three had received trypan red, two cantharidin, and two arsenic. All of these substances were given subcutaneously. One animal had been killed without having received any toxic dose because it showed a slight spontaneous albuminuria. In most cases the animals were killed rather than allowed to die spontaneously. That they had received sufficient poison to produce a renal lesion was shown by the occurrence in all of the animals of albuminuria and cylindruria of varying degree. The droplets stain intensely blue black with Mallory's

phosphotungstic acid hæmatoxylin stain, and resist decolorization with ferric chloride for a long time. With eosin and methylene blue they stain pale red. The exact nature of the droplets is not known. The very frequent occurrence of these hyaline droplets in the glomeruli of animals receiving uranium nitrate, and their absence in the other animals, suggests a direct causal relation between the lesion and the drug.

5, 6. The Serum Treatment of Epidemic Cerebrospinal Meningitis. - Dunn makes a report based on a series of forty consecutive cases of epidemic cerebrospinal meningitis treated with Dr. Flexner's antimeningitis serum. The disease may be divided into the following types: 1. The well known fulminating type, in which the progress of the disease was so rapid that the patients when seen were already in an extremely serious condition, with profound coma and weak heart (three cases). 2. Severe cases, in which the patients were unconscious, or in violent delirium, with poor general condition (six cases). 3. The common type, in which the patients were not unconscious, but very apathetic or in mild delirium, with fairly good general condition when seen (nineteen cases). 4. The mild type, in which the patients were perfectly rational, with headache, rigidity, or retraction, and good general condition (six cases). 5. The chronic type, in which the patients were seen late in the course of the disease. unconscious, but without fever or active symptoms (six cases). The nine fatal cases in the series throw a certain amount of light on the limitations of the value of the serum. Of these nine, five were cases seen late in the course of the disease, at a time when the patients were in the well known chronic stage. unconscious, and without fever or active symptoms. In one of these the serum was not given until the patient was actually moribund. Of the other four cases, one was of the fulminating type, one a very severe case, and one patient died of an intercurrent bronchopneumonia, coming on after the temperature had come down to normal and all meningeal symptoms had subsided. The last case was one of average severity, in which the serum appeared to produce a slight improvement in the beginning, but

which later appeared uninfluenced by the antiserum. advanced into the chronic stage, and a fatal result ensued after many weeks of illness. The author's belief in the great value of the Flexner antimeningitis serum is based not chiefly on its apparent effect on the mortality of the disease, but on the very marked and striking effect which its use appears to produce in individual cases. It so modifies and changes the course of the disease as to present a very sharp contrast with the course usually seen in cerebrospinal meningitis treated by other methods. The three principal effects of the use of the serum seem to be: First, to produce a fall of temperature; second, to produce a rapid improvement in the patient's general condition, accompanied by a more or less marked relief of certain symptoms; and third, to cut short the course of the disease. Another notable effect of the serum is seen in the successive examinations of the cerebrospinal fluid during the period of its use. This effect is most striking in early cases, in which the cerebrospinal fluid contains large numbers of diplococci. In such a case a great many intracellular diplococci are observed in the fluid withdrawn by the first lumbar puncture. Twenty-four hours after the first injection the fluid presents a strikingly different picture. The whole number of organisms seen is much smaller, but the chief change is that the majority are intracellular, only rare extracellular forms being seen. The third lumbar puncture shows still fewer diplococci, and those only intracellular. In the fourth fluid, after three doses there are frequently no diplococci to be found, or, at most, very rare intracellular forms. As to the amount of serum which should be given, the author was at first afraid to inject amounts larger than the quantity of cerebrospinal fluid withdrawn. After several patients, to whom small doses had been given, had shown a less favorable course, more prolonged illness, and a tendency to relapse, he began to use larger doses. A few patients showed signs of collapse immediately after an injection, but in no case were these signs of long duration, nor did they end in death. He believes that 30 c.c. can be given usually with perfect safety, even when smaller amounts of fluid are withdrawn. He has given, without any bad results, as much as this when no fluid was withdrawn. One can judge to a certain extent now far it is safe to go by the feeling of resistance to the injection of the serum. In cases in which larger amounts of fluid are withdrawn he believes 45 c.c. should be given at a dose. The daily injection of the serum in most cases seemed to be effective. After four doses have been given, if, after one or two days the case proves resistant, or at any time if there is a tendency to relapse, this treatment should be repeated. It is a question whether in some severe cases the serum should not be administered oftener than once in twenty-four hours. In two very severe cases death occurred in spite of the early use of the serum. In both of these cases a notable improvement was shown after the first dose and continued up to within a few hours of the time he arrived to give the second injection. Then both patients began to grow rapidly worse, so that then the second injection was given the condition of each was practically hopeless. He thinks it is possible these patients might have been saved by more frequent use of the serum, and he believes fulminating cases should be very closely watched and provision made for giving a second dose at any time. Dunn concludes that the use of the Flexner antiserum is of great value in epidemic cerebrospinal meningitis. He believes its value to be comparable to that of diphtheria antitoxine in diphtheria. The use of the serum at times aborts the disease, frequently rapidly relieves its symptoms, shortens its course, lessens the liability to sequelæ, and greatly reduces its mortality. 3. The serum should be used as early as possible in all cases, even of suspected epidemic meningitis. 4. It should be frequently repeated as long as there are symptoms or any tendency to relapse. 5. Late chronic cases are unfavorable for the use of the serum, but any case in which the diplococci are present has some hope of relief by its use. 6. Some cases are resistant.-Churchill reports his experience with eleven patients suffering with meningococcic meningitis, whom he treated with Flexner's serum. As a rule, the patients were more comfortable after a puncture and injection, though in one or two of the cases this did not take place for several hours after the puncture. The immediate effect of this procedure seemed to stir up the patient. None of the punctures were done under an anæsthetic, but he believes that there would be considerable saving of wear and tear in certain patients if they were given an anæsthetic, for example, those not very toxic, but in a fairly conscious condition. The first sign of permanent improvement noticed in at least five of the patients was a clearing up of the mental condition. They became perfectly rational after an injection (not always the first one), were more quiet, while the rigidities were still very marked. It was a curious sight to see the patient lying in bed with head strongly retracted, yet with no expression of pain; quiet, looking about, and interested in the ward doings. Churchill concludes that, taken with the cases already reported by Flexner and the other investigators, the results of this treatment of meningococcic meningitis are most remarkable. As one watches the behavior of these patients after one, two, or three injections of this serum, he is impressed with the astonishing change which comes over them, the clearing mentality, the unsuffering expression of countenance, the evident comfort, even with a still retracted head and rigid muscles, and he is filled with an optimism as to the ultimate result. Enough has been done by the serum to warrant its use on a wide scale, and it is not too strong a statement to make that, given a case suspected to be meningitis, it is our duty to do a lumbar puncture and, if we get a cloudy fluid, to inject the serum at once and repeat it if bacteriological examination prove the case to be one of the meningococcic variety.

7. Observations on the Thyreoid and the Parathyreoids.—Tuholske remarks that ligation of the thyreoid veins produces dilatation of the capillaries with increased pressure, transudation of blood plasma through the endothelial capillary tubes into the extravascular spaces until the pressure of the plasma in the intercellular spaces equals the pressure in the capillaries. We might count on the exape of some extravascular fluid by the lymphatics. The effect of the transudate at first is a mechanical

one; there is a crowding of the cells, an interference with oxygen admission, the retention of carbonic acid, and asphyxia. In this condition the vagrant or indifferent cells, the least fit to survive, suffer a degenerative process and die, while the limitation of arterial afflux brings the gland cells from hyperactivity to the normal. As part of the process the connective tissue stroma would increase and, in the later contraction, lessen the size of the gland-in other words, restore it to a condition near the nor-The result of the experiments on dogs distinctly demonstrates the success of the procedure, which in reality consists in the production of a Bier's passive hyperæmia.

The Miracles at the Tomb of B. François de Paris.-Collins observes that, studied in the light of our present day knowledge of the clinical manifestations of hysteria, there is very little in the records of the miracles wrought at the tombs of sacred appellants or by "secour" that transcends our understanding. The investigations of neurologists, and particularly those of France, have shown that the subjective and objective symptoms which the various individuals whose histories are related in such detail by M. de Mongeron, are those that constitute the signs and the symptoms of the "attack" of the disease. These signs have such definite characteristics and associations that they are rarely to be confounded with those of organic disease. Such characteristics and associations are to be found in every case related in extenso by de Mongeron. The "representations," the ecstatic states, the epileptoid state, the state of contortions and passionate attitudes, and the state of delirium, which are described in such detail, are no less and no more typical and characteristic than those described in such monographs as that of Paul Richer on major hysteria. After an examination of the literature of previous centuries, one reads with amazement the statements of strayed theologians and semiphysicians, that functional nervous diseases are increasing rapidly at the present time. They cite in substantiation of such alleged increase the fact that psychasthenia was not to be found in any standard dictionary until 1901, and thoat neurasthenia came into being only a generation ago. If their opinion and judgment concerning existing conditions are no more reliable than those of the past, they need not be taken very seri-

A Suggestion as to the Dietetic Treatment in Dilatation of the Œsophagus.—Einhorn re-

marks that if from the dilated œsophagus fluids do not get into the stomach, the failure may be caused by one of two things: (1) Lack of peristalsis of the œsophageal muscles; (2) hermetic closure at the upper or lower part of the œsophagus. The closure need not be-and usually is not-of an organic nature, and bougies or sounds do not find any difficulty in passing the entire canal. The walls of the cesophagus may, however, lie in such close apposition or may be folded in such a manner either at the beginning or at the cardiac end, that is absolutely air tight. This prevents fluid from escaping from the cesophagus, just as from a pipette nothing can drop if we close the upper end with the thumb. To facilitate the drainage of the esophagus into the stomach, all hermetic closure of the œsophagus must be overcome and a continuous canal between the two organs must be established. The drainage tube is constructed in the following manner: A soft rubber tube 30 mm. in diameter and 21 inches in length is provided with a large number of apertures from the lowest part to 7 inches above it. There are two marks at 17 and 21 inches from the end, and the entire tube is provided with a mandrin. The drainage tube with mandrin is introduced by the patient himself immediately after taking fluid or semifluid food. The mandrin is then removed and the tube is moved up and down for about half to one minute between the marks at 17 and 21 inches, and is then withdrawn. Moving the tube to and fro hastens this process, as it tends to eliminate the closure at the cardia.

By J. G. TURNER.

Tuberculosis of the Hip.—Bowlby gives his experience in the treatment of hip disease in children under twelve years of age at the Alexandra Hospital. This hospital was founded in 1867, with the object of treating tuberculous disease of the hip without operation other than the opening of abscesses-that is, by rest and by extension, and by good nursing and food; and it was stipulated that the length of time the children were to remain in the hospital was to be in no way limited. In 1879 the Clinical Society instituted an investigation into the relative merits of nonoperative and operative (by excision) treatment of tuberculosis of the hip.

In the Alexandra Hospital from 1867 to 1879 the mortality of nonoperative cases was twenty-six per cent. The writer became connected with the hospital in 1887. Since then he has treated 900 cases, with a mortality of less than four per cent. Not one of the patients has been treated by excision of the hip joint. No child was discharged unless all the active signs appeared to be at an end, and all children were made to walk on crutches for at least one year after it was no longer necessary to confine them to bed. If, when improvement had set in and the acute stage of the disease was past and pain had disappeared, the child was allowed to walk too soon there was apt to be a return of the symptoms. No child was discharged who had to wear a splint; a Thomas's splint never takes the place efficiently of complete rest in the recumbent position and the application of extension. All the discharged children were kept under observation, in some instances for many years, and were readmitted if there was any recurrence of the pain, a residual abscess, etc. Disease of both hips made treatment very unsatisfactory, as it was impossible to get the child up as soon as if it had one sound limb on which to walk with the aid of crutches. Disease of both hips indicated a peculiar susceptibility to tuberculosis, many such children having spinal caries in addition. Pulmonary tuberculosis was hardly met with at all, and very few of the children had tuberculous disease of the glands of the neck, the disease appearing to expend itself on the osseous tissues. But it does not do to suppose for a moment that a child who has tuberculosis of the hip has that tuberculous lesion only. So that we must try and treat the child himself, and not merely the hip disease. many cases the patient can cure the tubercle that is in him if only he is given sufficient help. In opening abscesses antiseptic surgery should have its fullest possible scope. If pyogenic organisms obtain an entrance to a place where there is tuberculous disease, they have an infinitely greater opportunity of destroying the tissues than in healthy people. Not only does tuberculosis predispose the tissues to this successful invasion, but the pyogenic organisms, in their turn, damage the tissues and allow them to be more easily invaded by tubercle. The line of treatment adopted at the Alexandra Hospital is as follows: First, there is absolute rest in the recumbent position, the child not even being allowed to sit up at all, such sitting up meaning movement at the hip joint. The joints involved are kept absolutely quiet, splints being used at first to ensure this if necessary. Extension is applied in the long axis of the limb in the position in which that limb lies most easily. As the muscles allow the limb to come into a better position the leg is got to lie flat on the bed, the object of this being to put the limb into the best position for subsequent progression, supposing that the joint is stiff ultimately. The amount of weight to be applied to the limb to effect extension is small. Very few children require more than two pounds; no child under the age of twelve years will require more than four pounds, and that only for a short time. Abscesses should be opened aseptically, and the contents having been cleared out most completely and yer gently, adequate drainage for a few days should be provided for In many cases the drainage

tubes can be removed within a week or so. There is too great a tendency to make multiple incisions, and it should not be done as a rule unless the abscess comes very close to the skin at two or more points. The general treatment means good food; careful nursing, very great care in the dressing of wounds, a certain amount of iron and cod liver oil, sending them away to country convalescent homes, and treating them as much as possible in the open air. The extent or degree of completeness of recovery is largely dependent upon the age at which the disease attacks the patient and upon the length of time it has been going on before treatment is commenced. The earlier the child is attacked by the disease, the more likely it is to have some permanent lameness. In very small children, where the head of the bone is tiny, only a moderate amount of disease will spoil the whole head of the bone. But if the child is from seven to eight years and the case is taken early, in a large proportion the child recovers with a thoroughly useful limb. The writer holds that the operation of excision is unsound. Excision of the hip is never actually performed, the only bone removed being the head of the femur. There is no possibility of sawing off the acetabulum, and at best it is only scraped. Again, in order to get clear of all tubercle and to avoid infecting the surrounding tissues, much more bone must be removed than is actually diseased.

Acidity of the Urine,
A Case of Sarcoma of the Right Os Innominatum

Simulating Appendix Abscess, By E. H. R. HARRIES.

1. Melitensis Septicæmia.—Eyre, in the second of the Melroy lectures, takes up the symptoms, etc., of Malta or Mediterranean fever. Of the clinical appearances the most important and indeed the only one that aspires to constancy, is the repeated alternation of pyrexial attacks with periods of normal or nearly normal temperature. In this respect the disease compares closely with typhoid with many relapses. The character and duration of the fever often vary considerably throughout the course of the disease, so that while in many cases the fever is of the remittent type, in others it is intermittent; in some it is continuously high, and in a few continuously low; at almost any stage of the disease one type of pyrexia may give place to another. The Micrococcus melitensis and its products appear to have a selective influence upon the nerve tissue, more particularly peripheral, but also central, and neuritis in some form or position is noted in at least one half the cases. The neuritis, usually of the sciatic, less frequently of the circumflex and peroneal nerves, commences suddenly and severely; the acute symptoms pass off rapidly, leaving a subacute or chronic affection of the nerve which may continue

long after the convalescence has otherwise been established. Such a neuritis is particularly liable to exacerbation in response to alterations in atmospheric conditions. Čutaneous and deep reflexes are usually increased. In long continued attacks headache, insomnia, nervous prostration, and mental incapacity are common sequelæ and point to the effect of the disease on the central nervous system. The respiratory and urinary systems are usually unaffected. Effusions into joints, particularly those of the shoulder, knee, and ankle, often occur in the course of the disease, and the specific micrococcus has been isolated in the fluid. The costosternal and costochondral articulations are also frequently affected and sometimes suppurate. But the "rheumatism" so frequently noted in Malta fever is in the majority of cases neuritis pure and simple. Effusion into the tendon sheaths at the wrist and ankle is sometimes noted. The sexual system shares in the general nervous irritability, and priapism leading to masturbation is said to be common. Orchitis and epididymitis are common metatases. Hyperpyrexia and cardiac failure are the only direct complications of a serious nature. Pyogenic foci due to the specific micrococcus are uncommon, the small skin furuncles of such frequent occurrence being due to staphylococci. In the early stages of the disease the diagnosis from malaria, typhoid fever, miliary tuberculosis, acute rheumatism, or septicæmia due to some other microorganism by the clinical symptoms alone is well nigh impossible. Consequently the diagnosis of Malta fever is based upon (1) the agglutination reaction, that is to say, the agglomeration of the individual cocci present in a laboratory cultivation of the specific micrococcus by certain specific antibodies-agglutinins-present in the blood serum of the patient; (2) the isolation of the Micrococcus melitensis from the blood of the peripheral circulation, from the splenic pulp, or from the urine and fæces. The prognosis of Malta fever, as far as life is concerned, is good. The mortality of the disease is not more than two per cent. of the gross incidence. Not more than ten per cent. are convalescent within one month; in fifty per cent. the disease lasts two months, in twenty-five three months, and in the remainder more than that. Of drug treatment there is none. Cold baths or cold packs should be used every three hours, while the temperature is over 103° F.

6. Acidity of the Urine.-Watkins states that for some years the French have alleged to have obtained very marked success in the treatment of certain diseases by the administration of the various combinations of phosphorus, which are selected according to the degree of the acidity of the urine. The treatment is based upon the assumption that the blood is a definitely acid fluid, and that the reaction of the urine is an index to the state of the blood. The so called alkalinity of the blood is due to the presence of the bicarbonates, which are acid The acidity of the blood is mainly due to the presence of acid phosphates, but their acid reaction to litmus is masked, owing to excess of the bicarbonates, which turn red litmus blue. The estimation of the acidity of the urine per litre is carried out by Boussingault's method of titration with a standardized solution of calcium sucrate. The end reaction is indicated by the appearance of a faint haze, which

is caused by the precipitation of tricalcium phos-This method does not estimate the total quantity of acids present, but it represents the power which the urine has of dissolving tricalcium phosphate, which latter is the physiological acidity, the practical medical acidity. It is important that patients suffering from a loss of phosphates should take a diet rich in these salts. As regards drugs, phosphoric acid and its salts, according to the degree of acidity of the urine, are all useful. The diseases most amenable to this treatment are neurasthenia, chronic arthritis, diabetes mellitus, chronic eczema, psoriasis, fermentative dyspepsia, and gout. The author reports a number of illustrative cases, showing the good results obtained by the administration of various forms of phosphoric acid.

The Characteristics of the Venous Pulse in Hypertrophy of the Left Heart Associated with Renal Heart and with Aortic Insufficiency, By BARD.

Venous Pulse in Hypertrophy of the Left **Heart.**—Bard is of the opinion that the tracings of the venous pulsation, which have been generally neglected, are of equal if not superior value to the cardiograms of the ventricle and the sphygmograms of the arteries. They do not reveal pathological lesions of the right heart, but present well marked characteristics in certain lesions of the left heart, particularly in hypertrophies of renal origin and in those which accompany aortic insufficiency. Bard first shows a tracing of the physiological venous pulse, and then goes on to describe and illustrate the variations met with in several pathological conditions, with special reference to those mentioned, and presents his explanation of the same.

Concerning the Practical Signification of the Measurement of the Blood Pressure in the Physical Therapy, By A. LAQUEUR.

- I. Theory of Opsonins.—Neufeld says that the appearance of opsonins in the specific treatment with tuberculin and dead staphylococci is to be considered at the present time only in the sense that we in like manner conclude from the appearance of agglutinins the presence of a specific process of reaction in the organism, without seeing in the opsonins with certainty the immune bodies which immediately call forth the process of healing, or to directly assume that the quantity of the same is a direct indication of the degree of the immunity produced
- 4. Toxic Osteoperiostitis Ossificans in Chronic Jaundice.—Beuttenmüller reports three cases, the first that of a man forty-seven years of age, who had had chronic jaundice for three years, during the last six months of which his hands and feet had gradually and painlessly increased in size. When he came under observation his hands were greatly enlarged and resembled paws, the fingers were thickened so as to resemble sausages, the terminal phalanges not especially swollen. The feet and toes were similarly affected. There were marked swellings of the distal epiphyses of the forearms and legs which were not painful or tender to pressure. The second patient was fifty-six years old, and suffered from many symptoms which seemed to indicate carcinoma of the biliary passages. The fingers were clubbed. The third patient was a woman, twenty-four years of age, who had suffered from chronic jaundice for over a year, and had a slight degree of clubbed fingers. The diagnosis made was that of biliary cirrhosis, with possibly a cholangitis.
- 6. Constriction Paralysis.—Oberndörffer reports a case in which a slight paresis of the median nerve and a serious paresis of the ulnar of the right arm, together with atrophy of the muscles supplied, was produced by the constriction of the arm of a man, twenty-eight years old, with ropes by the police while endeavoring to control him while drunk and disorderly.

- 1. Histogenesis of Myeloid Leuchæmia.-Schridde says that myeloid leuchæmia is to be considered as a systemic disease belonging to the large class of metaplasias. The leuchæmic cell proliferations spring from capillary cells, from which they form themselves through heteroplasia or indirect metaplasia. Thus we can speak of the myeloid leuchæmic proliferations in the different organs as true myeloid metaplasias.
- 3. Hæmolytic Complement in Human Milk .--Pfaundler and Moro assert that in almost all tests with human milk the hæmolytic complement was demonstrated.
- 5. New Clinical Method for the Determination of Opsonins.--Kämmerer suggests the following method: I, The serum is obtained and centrifuged in the usual way. 2, An emulsion of bacilli is prepared, not in the usual physiological salt solution, but in a 1.5 per cent. solution of sodium citrate. This emulsion must not be too thick nor too thin. 3, The blood from one and the same person is taken at the same time from the finger and added to the other substances in the Wright's capillary pipettes. Each pipette is marked and will contain: pipette, two parts blood of healthy person A, one part immune serum, one part emulsion of bacteria. Second pipette, two parts blood of healthy person A. one part normal serum, one part emulsion of bacte-The mixing is done according to Wright's method; the presence of the emulsion of bacteria prevents coagulation. Quick work is necessary. The pipettes are sealed and placed for half an hour in the oven. Examinations are best made on cover glasses with Canada balsam, as its transparency assists in the counting. The contents of the two pipettes differ only in that the one contains immune serum and the other normal serum.
- The Cutaneous and Percutaneous Tuberculin Reactions.—Emmerich says that the ointment reaction of Moro furnishes a markedly less number of positive reactions in individuals who are clinically free from tuberculosis, that it is more easily applied than the cutaneous inoculation and is absolutely harmless, that it is more apt to fail in progressive tuberculosis than the cutaneous inoculation, and that it is useful for diagnostic purposes in adults only to a limited degree.

 By HEIMANN. Simple Aid in Obstetrics,

New Points in the Treatment of Suppurative By BERGEL, MÜLLER, and PEISER. 14. Historical Contribution to the Study of Perityphlitis, By MULLER.

Typhus Bacilli in the Blood of Persons Not Suffering from Typhoid Fever.—Busse reports four cases, two of miliary tuberculosis, one of consumption, and one of pneumonia, in which typhus bacilli were found in the blood, although none of the three were suffering from typhoid fever. These cases prove that the presence of typhus bacilli in the blood is not a positive proof that the patient is suffering from typhoid fever.

2. Congenital Word Blindness.-Peters reports a case of this nature met with in a boy, twelve years of age, and also a doubtful case, in a boy eleven years of age, which illustrates the difficulties met with in the distinction of this condition.

Severe Hæmorrhages During Labor. -Schickele reports several cases of severe hæmorrhage during labor, and concludes that the condition of the general nutrition, the bodily strength, and healthy organs play an important part in the prognosis. Women who have frequently borne children, particularly those who have borne children almost yearly, and very emphatically those who have had severe hæmorrhages during previous labors, are greatly endangered by a renewed hæmorrhage. Cases of placenta prævia which have lost blood several times before delivery have an uncertain prognosis. It is bad when the pulse is accelerated. Finally he remarks that it is noticeable how much better the abundant hæmorrhages are borne in cases of ruptured extrauterine pregnancy.

6. The Vaccine Test.—Knöpfelmacher asserts that in doubtful cases the vaccine test by subcutaneous injection is competent to distinguish between the sickness produced by cow pox and smallpox in a nonvaccinated person.

7. After Treatment of Laparotomies.-Jerusalem applies to the region of the scar an oval suction glass and keeps it in place for twenty to thirty minutes every two or three days. He states that after several of these applications, from six to twenty-two in his cases, the tenderness disappears, resistance is no longer felt, the scar becomes softer, and the patients are freed from pain. Obstinate obstipation is benefited by the same means.

Subcutaneous Total Rupture of the Brachial Plexus.-Weber reports the case of a man, thirty-nine years of age, who was thrown from an automobile and was taken in an unconscious condition to the hospital. The surgeon found two fractures of the left arm, one about the elbow joint, the other of the radius. These fractures were reduced and, a proper dressing applied. When the dressing was removed four weeks later the hand, forearm, and arm were found to be paralyzed, together with the muscles of the shoulder. All the muscles supplied by the brachial plexus were involved, and there was a total loss of sensibility over the same area. No trace of injury to the vertebra, scapula, clavicle, or humerus could be detected even with the x rays, but a little above the middle of the clavicle there was a tender point with abnormal resistance, which Weber believes to have been the site of the rupture of the plexus.

14. Historical Contribution to the Study of Perityphlitis. - Müller's contribution is the presentation of two cases reported by Schönlein of what would naturally be taken to be appendicular inflammation from the symptoms which were treated in 1841 for rheumatism of the abdominal muscles. Both recovered, the second after rupture of the abscess into the intestine, as shown by the passage per

rectum of a large amount of pus.

By E. S. STONE.

I. The Use and Abuse of Digitalis .- Janeway considers digitalis as one of the few indispensable drugs. The causes for its failure to give satisfaction are: (1) The use of inefficient preparations. (2) Use in unsuitable cases. (3) Improper dosage. (4) Improper methods of administration. (5) Neglect of other necessary therapeutic measures. following conditions must be fulfilled in order to get good results from its use: (1) The leaves must be from plants of the second year's growth, picked at the beginning of efflorescence, free from stalks, and carefully dried. (2) The dried leaves must be kept absolutely dark and free from moisture in sealed tin or glass containers, and for not more than one year. (3) The preparation dispensed must be freshly made from these leaves exactly as prescribed by the Dispensatory. The infusion, the tincture, and the powdered leaves are the trustworthy forms for administration. The action of digitalis is to increase contractility, tone, and irritability. It must not be given to slow the heart in tachycardia, or in fever, to produce diuresis in acute nephritis, or to remove an inflammatory pleural effusion. With rapid heart action it must be used only when there is insufficiency of the ventricles. Two drachms of a good infusion is a sufficient dose. It should never be pushed more than a few days without careful record of heart and pulse rate and of fluids taken and urine passed each twenty-four hours. In addition to the proper use of the drug, one should combine psychotherapy, cheer-

fulness, courage, and hope.

2. The Clinical Study of Heart Cases.-Conner believes that one should inquire not only into the existing subjective symptoms, but into the earlier history of the patient as well. Auscultation is believed to be sometimes a means of confusing and concealing a diagnosis. The importance is emphasized of studying the disturbances of the right side of the heart by means of the clinical polygraph. Orthodiography with the x rays is also of importance in studying the size, position, and form of the heart under normal and pathological conditions. Percussion is of the utmost importance, in order to outline both the relative and absolute dulness. The measurements of the heart which are of chief importance are: (1) The long diameter, the distance from the true apex to the point of junction between the upper right border of heart dulness and that of the great vessels. (2) The distance from the midsternal line to the point of dulness farthest to the right. (3) The distance from the midsternal line to the point of dulness farthest to the left. As to auscultation in mitral stenosis with tricuspid insufficiency, and a systolic venous pulse, the absence of presystolic mitral murmur means paralysis of the auricles. With

tricuspid insufficiency the systolic murmur at the

base of the sternum is often absent. A faint dias-

tolic murmur inaudible through the stethoscope may

often be heard through the naked ear. 3. Irregularities of the Heart Resulting from Disturbed Conductivity.—Erlanger quotes Gaskell, who concludes that in the normal heart of cold blooded animals the perceptible interval between the beats of the several chambers, sinus and auricles, auricles and ventricles, is due to the existence in their junctions of a natural block to the passage of the impulse. In the mammalian heart it can be shown that interference with the conduction of the excitation wave is due to two blocking points, one at the junction of the rudiments of the sinus with the auricles, the other at the junction of the auricles with the ventricles. Partial and complete block may be established experimentally between any two parts of the heart, provided one of the parts is spontaneously rhythmical, by narrowing the junctional connection between them. The same forms of block may probably be produced by pathological processes which sever the functional connection of one part with another. A transitory block being established by a lesion, the less rhythmical part at first stops beating, but if it possesses spontaneous rhythmicity it soon begins to beat again, first in complete block and then in partial block with all the rhythms observed, for example, in the transitory auriculoven-

5. Primary Carcinoma of the Vermiform Appendix .- McWilliams found the sexes about equally divided in seventy-seven cases of primary cancer of the appendix. Concretions have no discoverable ætiological importance in this form of cancer. The disease develops most frequently at the site of strictures, obliterations of the tip, and chronic inflammatory lesions. Enlarged lymphatic glands were present in nine per cent. of his analyzed cases. Primary cancer of the appendix occurs in 0.4 per cent. of the appendices operated on. Of the cancers found at the appendix twenty-two per cent. were columnar cell, fifty-three per cent. spheroidal cell, nine per cent. of the transitional type, and four per cent. colloid. The disease tends to infiltrate contiguous structures, but not to produce distant metastases. Secondary growths were found in six and six tenths per cent, of the cases. There was very little tendency to recurrence in the cases which had been operated upon. In forty-six operations by the author there was no mortality. A diagnosis cannot be made prior to operation, but in any suspicious case the exsection should be as wide as possible. It is impossible to say, at present, whether cancer is primary or secondary to coincidental chronic inflammatory lesions.

8. Torsion of Appendices Epiploicæ and Its Consequences.—Briggs reaches the following conclusions: I. Torsion of appendices epiploicæ is more frequent than the meager literature of the subject would reply. 2. It usually occurs in persons who are somewhat obese during and after middle life. 3. Intraabdominal torsion of these structures may simulate appendicitis, hepatic colic, cholecystitis, and various other intraabdominal diseases. Torsion of these structures in a hernial sac may cause all the local symptoms of an acute omental or intestinal, femoral, or inguinal hernia. 4. Torsion of these structures may result in adhesions and bands, and their usual consequences. 5. The masses of fat may become infected and cause general peritonitis. 6. In the present state of our knowledge an accurate diagnosis of torsion of these bodies prior to operation would seldom be possible. 7. An operation is always indicated at the earliest possible mo-

- By G. C. Waiss.
- Pyelitis in Pregnancy and the Puerperium.
 Vineberg finds this disease not uncommon, though not generally recognized by the profession at large.

Its causation may consist in obstruction in some portion of the urinary tract, or in pathogenic bacteria. It has long been recognized that the pregnant uterus might compress the ureters, but the exact manner by which it is brought about is not definitely settled. As to infection, there may be as causative agent gonorrhœa, pus cocci, colon bacilli, or tubercle bacilli. The right kidney is affected in the majority of instances, and both kidneys in about 15 per cent. of all cases. There are two varieties of the disease, differing as to the onset, one being preceded by bladder disturbance and general malaise, the other coming suddenly, with chill and fever. The kidney may be sensitive, but is not usually enlarged. The urine may be high colored, albuminous, acid, with specific gravity of 1.006 to 1.020, pungent odor, and sediment of pus, epithelia, blood corpuscles, granular casts, and bacteria. The acute symptoms usually subside in a short time, but there may be recurrences during pregnancy or the puerperium. The condition should be distinguished from typhoid fever, appendicitis, and cholecystitis. The prognosis is good for the mother, but bad for the child. Rest, milk diet, ice bag over the kidney, and urotropin helmitol or some form of opiate may constitute the treatment.

3. Cæsarean Section.—Halpenny thinks this operation should be done: (1) In all cases of pelvic contraction with a conjugata vera of less than 5.5 centimetres. (2) In cases with conjugata vera between 5.5 and 7.5 centimetres in which the patient has not been infected, is not unduly reduced, and in which the child is living. (3) In cancer of the cervix with undilatable os. Craniotomy or embryotomy should be performed: (1) In cases of pelvic contraction, in which the conjugata vera is not less than 5.5 centimetres, and the child is not alive. (2) In cases of pelvic tumors which cannot be displaced from the pelvis under an anæsthetic. (3) In all cases in which the mother dies suddenly, the child being dead. (4) In central implantation of placenta prævia, the child being dead. (5) In dystocia, with dead child, due to ventrofixation or ventrosuspension. Vaginal Cæsarean section should be done in eclampsia cases with rigid os. Pubiotomy or symphyseotomy should be done in cases with conjugata vera of not less than 7 or 7.5 centimetres, the child being alive.

5. • The Diagnosis of Extrauterine Pregnancy. -Holden finds that there are no pathognomonic signs of this condition. The mass in the pelvis is the one sign which is invariably present. quently happens that a diagnosis can be made only by carefully questioning the patient as to all her symptoms, and then weighing the evidence for and against ectopic gestation. A clinical history is difficult to obtain if a woman is stupid, phlegmatic, or reticent. The most important symptoms are amenorrhœa, followed by an attack of severe abdominal pain, with subsequent vaginal hæmorrhage. If an unilateral mass is then observed in the pelvis there is probably an extra uterine pregnancy which has ruptured or undergone a tubal abortion. Diagnosis prior to rupture or tubal abortion will be made only in case there may be symptoms which suggest to the physician that a careful examination of the pelvis

should be made.

Proceedings of Societies.

AMERICAN GYN. ECOLOGICAL SOCIETY.

Thirty-third Annual Meeting, Held in Philadelphia on May 20 and 28, 1908.

The President, Dr. J. MONTGOMERY BALDY, of Philadelphia, in the Chair.

(Concluded from page 43.)

The President's Address alluded to the disappearance by death of most of the founders and early members of the society and the necessity of choosing wisely in filling their places. He thought there were now too many members on the Atlantic Coast. There were a scientific and a social side to each member. The latter was not unimportant. The Transactions of the society contained the best of all that had been done in gynæcological science. He questioned the value of two sessions for "symposia." It tended to develop abstracts rather than exhaustive papers, and directly interfered with the president's address. The great work which had been done in gynæcology forbade that it should pass as a distinct specialty. He now desired to recommend improvement in anæsthesia, by legislation if necessary, removing its dangers and increasing its usefulness. A salaried anæsthetist should be in every hospital, and a woman should be preferred for the position.

The Condition of the Mucosa in Cases of Uterine Myomata.—Dr. T. Cullen, of Baltimore, said that the condition of the mucous membrane was largely determined by the situation of the myoma. In large submucous myomata the mucous membrane was stretched, but not necessarily diseased; in some cases, however, it was hypertrophied. in others atrophied. In cases in which it was greatly compressed by a tumor it might disappear altogether. In mucous polypi, which were usually single and not very large, the mucous membrane was, of course, hypertrophied. The glands in such growths were usually normal. The course of events with submucous myomata was that the mucous membrane gradually became thin, the glands disappeared, then the stroma, and finally only the superficial epithelium was left. When this disappeared, sloughing and suppuration of the tumor would follow. The glands of the mucous membrane might become dilated and cystic. Hæmorrhage was due to stretching and rupture of the vessels, the veins being sometimes greatly dilated. In multiple submucous myomata the intermediate mucous membrane became greatly thickened. Endometritis with myomata was rare, except as a consequence of sloughing, or of association with pyosalpinx. Tuberculous disease as an associated condition was rare. Carcinoma of the uterine body had been found in connection with myoma twenty-five times.

Intraabdominal Pressure.—Dr. R. R. SMITH, of Grand Rapids, Mich., spoke of the ideas prevailing at present upon this subject, many of which were erroneous. Intraabdominal pressure was governed by the same mechanical laws which obtained outside the body. It might be positive or negative, that is, above or under fifteen pounds to the square inch. according to the mechanical conditions. In the horizontal posture there was little variation in the pressure, even with women at term. If the tissues were stretched in certain positions, the inside pressure would increase, but the pressure did not ordinarily increase in the presence of ascites and abdominal tumors. If in the presence of the conditions mentioned the position was changed from the standing to the knee chest or the horizontal, the inside pressure would increase. The pressure diminished or became negative when the abdomen was opened, especially in the lumbar region. The pressure was negative when pleural effusions depressed the diaphragm. The pressure was increased by muscular contractions of the abdominal wall.

Some Further Experimental Work in Severing the Pelvic Vessels in Bitches, and its Bearing on Ruptured Ectopic Gestation Sacs.—Dr. H. Robb, of Cleveland, reported that in this experimental work death had resulted only when blood was lost amounting to three per cent. of the bodily weight. Women who suffered with a ruptured tubal gestation sac seldom died from hæmorrhage, but from hæmorrhage and shock. In twenty-nine dogs which were experimented upon, there was no death from hæmorrhage alone. The anatomy of the dog's uterus was shown, and the method of dividing the uterine vessels in various positions. Hæmoglobin and other blood tests were made. The bleeding in fourteen experiments stopped within ten minutes, after which salt solution was injected. This was not followed by renewed hæmorrhage, and it had no influence on the clots already formed. In cases in which the hæmoglobin diminished, an occluding clot was always found in the divided vessels. It was inferred that in women with whom the hæmoglobin remained stationary an operation might with safety be deferred.

Vertical and Horizontal Amputation of the Uterus.-Dr. H. A. Kelly, of Baltimore, believed that in the nonmalignant diseases of the uterus a conservative line of treatment should be the rule. This should obtain particularly in women who were under forty, with whom it was desirable to preserve the function of menstruation. This could be done by subsection of the body of the uterus, retaining the body of the mucosa and reducing an excessive uterine flow to normal. The ordinary conservative operation upon the tubes and ovaries did not always have a well defined plan, and might not control a tendency to excessive hæmorrhage. The conservation of a portion of the uterus with fibroid disease gave excellent results with those who were still menstruating. The same was true in regard to the inflammatory or hypertrophic entanglement or subinvolution of the uterus, the mucous membrane being preserved for some distance above the os internum. The operation was of a grade between total and supravaginal hysterectomy. The resection might be horizontal or vertical, a wedge being removed from the middle of the organ and a circular or oval/stump being left, which was closed and then covered by peritonæum. The operation was also useful/for bad cases of prolapse of the uterus. In any dase, it left a small uterus, which was still competent for menstruation, the endometrium being preserved as far as possible. The horizontal section was not likely to be followed in pregrame: but the vertical section might be. It

was not asserted that this operation was a new suggestion, as similar procedures had been advocated by others.

Dr. A. Martin said that similar work had been done in Europe. He had often resected the uterus after myomectomy, but he had not published his cases, as he wished to see whether pregnancy would follow. The possibility of pregnancy was undoubted, but whether the pregnancy could go to term was another matter. Rupture would probably take place in some cases, and hence if pregnancy did occur, the case should be watched with the greatest care to guard against accident. He had performed his resections by the vaginal route. The patients had usually done well. Menstruation had continued for a short time, and then ceased. The stump was well covered with peritonæum, and as much of the operation was a desirable one for young women.

Dr. F. PFANNENSTIEL had performed the operation which had been described, and in most of his cases for chronic metritis. He had also performed it upon elderly women suffering with prolapsus. He removed a wedge of tissue, as described by Dr. Kelly, and left only a small portion of the body of

the uterus.

Dr. H. J. Boldt had been performing the operation for years, especially in young women. It was an advisable operation for the treatment of chronic fibrosis.

Dr. W. G. Wylie, of New York, preferred hysterectomy or myomectomy to the operation described. Even after these operations, menstruation might be continued, at least for a time. The influence of small fibroids during labor was slight. After the age of forty, there was danger of malignancy, and he would then prefer hysterectomy to Kelly's operation. The mucous membrane should be saved by any possible measure before the age of forty, and in many cases no operation would be required.

and in many cases no operation would be required. Dr. S. C. Gordon referred to the hypertropic or subinvoluted uterus as belonging to one of the classes of cases under discussion. He had treated that condition satisfactorily since 1884 by removing a wedge from either side of the cervix. In fibroid disease, if there were more than one or two tumors, he would advise hysterectomy, especially if the patient was older than thirty-five. He*was not favorable to the performance of the so called conservative operations. Too often it was necessary to operate again, and most women objected to this

Dr. J. R. Goffe saw no advantage in conservative surgery if the object was merely to retain a vaginal or even a menstrual discharge. To retain ovulation was another matter, as it meant the possibility of pregnancy.

Dr. A. L. Smith was opposed to so called conservative operations. It meant much trouble to the surgeon from the dissatisfaction of his patients, who

too frequently remained uncured.

Dr. E. H. Grandin thought the proposed operation identical with supravaginal hysterectomy. He believed the continuance of the menstrual discharge would be desirable for most women. He agreed with those who objected to partial operations. If the ovary was diseased, one should remove it entirely or let it alone.

Dr. C. C. Frederic thought there was no objection to leaving a few small fibroids in the uterus. Their presence was frequently not inconsistent with normal pregnancy and labor. He knew of but one case in which fibroids thus left had caused subsequent trouble. For young women myomectomy was

preferable to hysterectomy.

Dr. Kelly realized that he had only crystallized, as it were, the thoughts of others. He retained the endometrium as a distinct feature in this operation, and it thus differed from supravaginal hysterectomy. In more than 200 myomectomies, there had been subsequent trouble in only two per cent. of the cases, and pregnancy had resulted in twelve cases. He believed that women were much better when they continued to menstruate, and he had experienced little trouble with those who had required a

repetition of operations.

Six Cases of Cæsarean Section Necessitated by a Previous Ventrofixation.—Dr. E. B. CRAGIN, of New York, defined ventrosuspension as attachment of the uterus to the abdominal partition by a single ligature or cord of new tissue, and ventrofixation as attachment to the same by a broad band of tissue between the fundus and the parietal peritonæum. Either was unsafe, the latter eminently so, should pregnancy occur, for the uterus must develop under abnormal conditions. This implied possibilities of uterine rupture or abnormal and ineffectual labor, the normal mechanism of labor being entirely perverted. Dystocia might exist in the form of transverse presentation, ineffective labor, or obstructed labor. Of course, many women on whom the operation had been performed had experienced labor without dystocia, but, on the other hand, forty cases of Cæsarean section had been reported in which the operation was necessitated by ventrofixation. That dystocia following ventrofixation should occur six times in the experience of one man (the author), and be so marked as absolutely to indicate Cæsarean section, was evidence of the frequency of this sequel. The fixation operations had all been performed by different operators, thus eliminating the personal equation. Notwithstanding these bad results, ventrosuspension, which might in time become ventrofixation, was still frequently performed. Thus, a ventrosuspension which allowed an easy labor and normal puerperium in the first postoperative confinement, might become a ventrofixation, and demand a Cæsarean section, as had occurred in the last case of the author's series. The conclusion which logically follewed was that ventrofixation, and probably ventrosuspension, were not safe operations for the treatment of posterior displacements of the uterus during the childbearing age.

Dr. W. WILLIAMS, of Baltimore, had had an experience of four cases of dystocia dependent upon operations for ventrofixation. In two of the cases Cææsarean section had been required, while the other two were merely cases of very difficult labor.

Dr. R. C. Norris had seen two cases of dystocia resulting from ventrofixation. There were thick bands of new tissue in the anterior uterine wall in both these cases. He agreed with the reader of the paper that there were very many ventrofixation operations which were not followed by dystocia. He hardly thought that ventrosuspension should be

unqualifiedly condemned. The treatment of retrodisplacements by shortening the round ligaments was much the safer way of meeting the difficulty.

Dr. E. P. Davis had not only had experience with dystocia as a sequel of ventrofixation, but he had seen grave intestinal complications from the same source. He had the conviction that the operation

had no field in childbearing women.

Dr. H. D. FRY had seen thirty or forty cases of natural labor following ventrofixation, but he had also seen one case of Cæsarean section. Better than Cæsarean section was the plan of cutting the adhesions binding the uterus to the parietes whenever the diagnosis was made, and allowing labor to progress normally at term.

Dr. W. G. WYLIE stated that he had always been opposed to the operation, and had seen cases in which dystocia had occurred. These cases proved to him that his original opinion was the correct one. The operation was almost always followed by stretching of the uterus, and in many cases preg-

nancy was an impossibility.

Dr. G. C. Gordon did not favor the operation, but treated retrodisplacements of the uterus by

shortening the round ligaments.

Dr. A. L. SMITH was not opposed to the operation of ventrofixation, but did not think it appropriate for childbearing women.

Dr. CRAGIN said that it was possible to cut the tissues between the uterus and the abdominal parietes, but many of the cases were not seen until labor had begun. It was not within the intended scope of his paper to suggest a substitute for ventro-

fixation.

Is Pubiotomy a Justifiable Operation?-Dr. J. W. WILLIAMS, of Baltimore, had had an experience of thirteen cases of this operation, with no maternal deaths, and in only one case had a woman been seriously sick. He employed the Döderlein technique, and had observed hæmorrhage in only one case. The puerperium had been normal in only six of the cases, various minor difficulties having developed. The average duration of the puerperium had been thirty days. In all the cases the women began to walk by the end of the third week, and were dismissed in good condition less than a week later. In one third of the cases there was a permanent mobility between the cut ends of the bone. This did not interfere with locomotion, and perhaps was of assistance in permitting subsequent spontaneous delivery in one of the cases. In ten of the cases the patients were as well as before the operation; three had had subsequent deliveries. operation came into competition with premature induction of labor and other operations in favor of the child. Patients usually did well, unless infected. The feetal mortality was two per cent., which was greater than after the induction of labor, but, on the other hand, the children were better developed. and it would probably supersede that method of delivery. It was much better than symphysiotomy, both for child and mother. It was indicated only in cases in which the conjugata vera measured more than seven centimetres; hence it was not a competitor of the Cæsarean section. Its mortality was far lower than that of the last mentioned procedure, but the latter was to be preferred, if the case is seen just before labor began. It was par-

ticularly applicable to the border line cases, affording a safe method of delivery, after subjecting a patient to the test of several hours in the second stage of labor, while in Cæsarean section the mortality rose steadily with each hour that elapsed after the onset of labor. It compared favorably with craniotomy, the high forceps operation, symphysiotomy, and version. It should be a primary operation as an alternative to craniotomy; it should not be performed in cases of infection, and it should not be performed by the general practitioner.

Dr. E. G. GRANDIN objected to publiotomy as compared with Cæsarean section. He did not think it suitable for an elective operation. In the border line cases, Cæsarean section had less morbidity and less mortality. Induction of labor was to be preferred, if performed after manual dilatation, with version, followed by gauze packing in the uterus. He was willing to accept the author's statistics for

the present.

Dr. F. PFANNENSTIEL had performed the operation twenty-seven times, with no fœtal mortality. He limited the operation to cases in which the conjugata vera measured at least seven centimetres. It should not be performed in cases of infection or by the general practitioner, and should be used

only on special indications.

Dr. E. P. Davis thought that most of the border line cases should have the test of labor. This and other major obstetric operations should be done only by those who had had considerable experience in obstetric surgery. The teachers of obstetrics should caution students and young practitioners in regard to major operations without first having an expert consultation.

Dr. R. A. MURRAY did not think favorably of pubiotomy. He believed in giving a doubtful case the test of labor and then doing a suitable operation, if necessary, under proper precautions.

Dr. B. C. Hirst did not favor pubiotomy for the class of cases in which it had been recommended by the reader of the paper. He would much prefer the premature induction of labor. In this operation the fœtal mortality with him, in a large number of cases, had been no greater than at term. He approved of Cæsarean section in preference to pubiotomy, and thought the latter should be classed with symphysiotomy and performed as frequently as possible.

Dr. H. D. FRY was quite decided in his opposition to pubiotomy. It involved danger to the child in the extraction of the head, and there was also very considerable danger from hæmorrhage. It had a morbidity of fifty per cent., which was perhaps greater than that of any other obstetric operation, unless it was symphysiotomy. One of its possible or probable consequences was septic phlebitis, and it should be limited to cases in which Casarean section could not be performed. As an alternative between this and Cæsarean section, he would certainly prefer the latter, if no other operation had

Dr. R. C. NORRIS was not convinced by the statistical arguments of the paper, though he admitted that he was favorable in a moderate degree to pubiestern in the public bone had been divided, there was need of very careful obstetric work in cases in which this operation was selected. The head was often in the occipitoposterior position and would consequently require very skilful treatment. While he was in favor of pubiotomy in a limited number of cases as an operation of election, he was also in favor of induction of labor, and would not accept the former as a substitute for the latter. The treatment of cases in which either of these operations was to be performed must be governed by the nature of the cases and by the skill of the obstetrician.

Retters to the Editors.

MERCURY IN TUBERCULOUS DISEASE.

43 St. Mark's Place, New York, June 29, 1908.

To the Editors:

As the subject of mercury in the treatment of consumption is growing in interest and application, may I be permitted to call your attention to a short article entitled Syphilis 28. Tuberculosis, which appeared in the Medical Record, vol. xlviii, page 910,

That short paper contained a report of a case of tuberculosis (complicated with syphilis) which cleared up after fifty mercurial inunctions of a drachm each. The case was a bad case of consumption, and its rapid cure with mercury was to me and my medical friends little short of a miracle.

After the publication of my case, a physician from Elmira, N. Y., reported in the Medical Record a similar experience. If I remember correctly, mercury thereafter was used in consumption by several physicians in this and foreign cities with favorable ROBERT ABRAHAMS.

Book Antices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Diseases of the Breast With Special Reference to Cancer. By William L. Rodman, M. D., LL. D., Professor of Surgery in the Medicochirurgical College of Philadelphia, Professor of Surgery in the Woman's Medical College of Pennsylvania, etc. With Sixty-nine Plates, of which Twelve Are Printed in Colors, and Forty-two Other Illustrations. Philadelphia: P. Blakiston's Son & Co. 1998 Pp. 385 (Price, \$4.)

The author brings to the preparation of this volume the rich experience of twenty-five years' work in surgery, and he pays tribute to the teachings of the late Dr. Samuel D. Gross, who instilled into him a belief in the curability of malignant disease by free and wide removal.

The preliminary chapters are devoted to a description of the anatomy and physiology of the breast, inflammatory and tuberculous diseases, syphilis, actinomycosis, cysts, diffuse hypertrophy, and keloid; the remainder of the book discusses tumors in general. The author accepts Ribbert's classification as best for practical purposes, but uses War-

ren's classification, with some additions, in the text. Be the tumor benign or malignant, he believes it should be removed. In carcinoma he holds that plastic procedures are inadequate, disappointing, and inadequate to the pathological requirements necessary to deal with an infiltrating and disseminated malignant process. Palliative operations are useless, and no benefit has followed an operation for cancer en cuirasse. Inoperable cases may be treated by the x ray and by toxines. The work is most generously illustrated, many of the plates being in colors.

Abdominal Tuberculosis. By A. Ernest Maylard, M. B., B. S. (Lond.), Surgeon to the Victoria Infirmary, Glasgow, etc. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. xvi-360. (Price, \$4.)

The author is careful to explain at the outset that his book is to deal with tuberculous disease of al! the abdominal contents, not simply with such disease of the peritonæum, to which the term abdominai tuberculosis is sometimes unwarrantably restricted. The opening chapter is devoted to tuberculous disease in general, with special reference to modes of infection. Through most of the chapter there runs an apparent readiness to fall in with Koch's doctrine of the rarity of the transmission of the infection from the begine animal to man, and vice versa, but, in the light of recent investigations, it ends by leaving the question sub judice. The concluding chapter, too, by Dr. Walter K. Hunter, is on the subject of general tuberculous disease, but is limited to the matter of treatment. This last chapter is an admirable exposition of the present status of the therapeutics of the disease, both curative and prophylactic.

Between these two chapters lies the proper substance of the work. It is perhaps as good a presentment of the subject as could well be made by one man at the present time, but not marked by any striking feature. Fifty-one clinical histories of illustrative cases are introduced, and they are not too condensed for their purpose. The book is illustrated with fifty-seven half tone pictures, and they

are exceptionally excellent.

On pages 310 and 311 there is a very useful statement of the various theories as to the way in which simple abdominal section often proves beneficial in cases of tuberculous peritonitis. The author wisely says: "It is not possible to draw any positive conclusion regarding any one of these theories being more truly explanatory than another. There is this fact, however, that the cases in which success is most marked are those in which fluid is taken away, so that it would seem as if removal of some toxic agent gave the tissues a greater chance of overcoming such of the virus as remains.'

We are sorry that the author has not followed the Lancet's sensible suggestion, put forward several years ago, that it would be useful to attach different meanings to the words tubercular and tuberculous. using the former as synonymous with nodular and restricting the latter to the specific tuberculous disease. He uses the words indiscriminately, but tubercular far oftener than tuberculous. The proofreading throughout the book seems to us to have been rather carelessly performed, especially in the bibliographical lists. All things considered, however, the work is to be commended as a substantial addition to our literature of the subjects with which it deals.

Miscellann.

How to Enter the Medical Reserve Corps.-A Medical Reserve Corps, as a constituent part of the Medical Department of the army, is authorized by an act of Congress, approved April 23, 1908, entitled "An Act to increase the efficiency of the Medical Department of the United States Army.' Its provisions are as follows:

SEC. 7. That for the purpose of securing a reserve corps of medical officers available for military service, the President of the United States is authorized to issue commissions as first lieutenants therein to such graduates of reputable schools of medicine, citizens of the United States, as shall from time to time, upon examination to be prescribed by the Secretary of War, be found physically, mentally, and morally qualified to hold such commissions, the persons so commissioned to constitute and be known as the Medical Reserve Corps. The commissions so given shall confer upon the holders all the authority, rights, and privileges of commissioned officers of the like grade in the Medical Corps of the United States Army, except promotions, but only when called into active duty, as hereinafter provided, and during the period of such active duty. Officers of the Medical Reserve Corps shall have rank in said corps according to date of their commissions therein, and when employed on active duty, as hereinafter provided, shall rank next below all other officers of like grade in the United States Army: Provided, That contract surgeons now in the military service who receive the favorable recommendation of the surgeon general of the army shall be eligible for appointment in said reserve corps without further examination: Provided further, That any contract surgeon not over twentyseven years of age at date of his appointment as contract surgeon shall be eligible to appointment in

94

the regular corps. SEC. 8. That in emergencies the Secretary of War may order officers of the Medical Reserve Corps to active duty in the service of the United States in such numbers as the public interests may require, and may relieve them from such duty when their services are no longer necessary: Provided, That nothing in this act shall be construed as authorizing an officer of the Medical Reserve Corps to be ordered upon active duty as herein provided who is unwilling to accept such service, nor to prohibit an officer of the Medical Reserve Corps not designated for active duty from service with the militia, or with the volunteer troops of the United States, or in the service of the United States in any other capacity, but when so serving with the militia or with volunteer troops, or when employed in the service of the United States in any other capacity, an officer of the Medical Reserve Corps shall not be subject to call for duty under the terms of this section: And provided further, That the President is authorized to honorably discharge from the Medical Reserve Corps any officer thereof whose services are no longer required: And provided further, That officers of the Medical Reserve Corps who apply for appointment in the Medical Corps of the Army may, upon the recommendation of the surgean general, be placed on active duty by the Secretary of War and ordered to the Army Medical School for instruction and further examination to determine their fitness for commission in the Medical Corps: And provided further, That any officer of the Medical Reserve Corps who is subject to call and who shall be ordered upon active duty as herein provided and who shall be unwilling and refuse to accept such service shall forfeit his commission.

Sec. 9. That officers of the Medical Reserve Corps when called upon active duty in the service of the United States, as provided in section eight of this act, shall be subject to the laws, regulations, and orders for the government of the regular army, and during the period of such service shall be entitled to the pay and allowances of first lieutenants of the Medical Corps with increase for length of service now allowed by law, said increase to be computed only for time of active duty: Provided, That no officer of the Medical Reserve Corps shall be entitled to retirement or retirement pay, nor shall he be entitled to pension except for physical disability incurred in the line of duty while in active duty: And provided further. That nothing in this act shall be construed to prevent the appointment in time of war of medical officers of volunteers in such numbers and with such rank and pay as may be provided by law.

Officers of the Medical Reserve Corps have the rank of first lieutenant, mounted, and, when on active duty, receive the pay of that grade, namely, \$2,000 per annum, or \$166.66 a month.

At the end of five years' active service an increase of ten per cent. is received, making \$2,200 annually, or \$183.33 a month. This ten per cent. increase is given for each period of five years' active service, until at the end of twenty years the maximum increase of forty per cent. is received, making \$3.884.4 menth

Officers of the Medical Reserve Corps on active duty, in addition to their pay, are furnished with quarters either in kind or by commutation at the rate of \$36 a month. Fuel and light are also provided. When traveling on duty mileage is allowed, the amount usually being sufficient to cover all expenses of the journey.

On changing stations they are entitled to transportation for professional books and papers and

baggage, including household effects.

Being mounted officers, they are provided with horses and horse equipments when necessary. Groceries and other articles may be purchased from the commissary. Instruments and appliances and professional books and journals are liberally supplied for the use of all medical officers in the performance of their duties.

Leave of absence on full pay may be allowed at the discretion of the proper superior authority at the rate of one month per year. Absence from duty on account of sickness involves no loss of pay.

In addition to a limited number of officers of the Medical Reserve Corps who are on active duty with the army in time of peace, it is desired to maintain a list of qualified men all over the country who are willing to serve as medical officers in time of emergency. To such men the President is authorized to issue commissions, and it is expected that, as long as they are under commission, they may be relied upon to give service when called. Officers of the Medical Reserve Corps cannot be compelled to accept active service, but should it be declined when offered, the commission will be vacated. Nothing prevents Medical Reserve Corps officers serving with the militia, or with the volunteer troops of the United States, or in the service of the United States in any other capacity, and when so serving or employed they are not subject to call for active duty with the army. Officers of the Medical Reserve Corps who make application for active service may receive such assignment when the necessity exists.

Approved candidates for the Medical Corps who have fulfilled the entrance requirements will be temporarily commissioned as first lieutenants of the Medical Reserve Corps until they have passed through the Army Medical School and their fitness for the Medical Corps has been finally determined. (See circular of information for candidates for the Medical Corps.)

Appointment to the Medical Reserve Corps of the Army is made by the President after the applicant has passed a successful examination before an examining board detailed from the Medical Corps of the Army and has been recommended by the sur-

geon general.

Permission to appear before the board is obtained by letter to the adjutant general of the army, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident. He must also furnish certificates, based on personal acquaintanceship, from at least two reputable persons as to his citizenship, character, and habits.

An applicant for appointment in the Medical Reserve Corps must be between twenty-two and forty-five years of age, a citizen of the United States. a

graduate of a reputable medical school legally authorized to confer the degree of doctor of medicine, and must have qualified to practise medicine in the State in which he resides.

The examinations for appointment in the Medical Reserve Corps will be held from time to time at convenient places throughout the country and will

embrace the following:

1. Physical examination. This will be thorough and will conform to that required for officers of the

army in general.

2. Examination of diplomas, certificates from State examining boards, certificates of membership in medical societies, and any other certificates or testimonials which the applicant may wish to submit.

3. An examination on the following practical subjects:

(a) Practice of medicine, including ætiology, clinical description, pathology, and treatment of diseases.

(b) Surgery—principles and practice.

(c) Obstetrics and gynæcology.

(d) Hygiene—personal and general, especially as to the prophylaxis of the more prevalent epidemic diseases.

This examination will be oral and sufficiently comprehensive to determine whether, in the opinino of the board, the applicant is (or is not) qualified to practise his profession under the usual conditions of the military service.

Should the oral examination in any subject be unsatisfactory the applicant may be required to take a written examination on that subject.

Successful candidates will be recommended to

the President for commission.

It is recognized that, except for the limited number of Medical Reserve Corps officers who are on active duty in the army, in time of peace there are few material inducements for representative physicians to apply for appointment in the corps. The possession of a commission from the President of the United States setting forth his confidence in the patriotism, fidelity, and abilities of the holder is, however, something that any one might be proud of, and the contact that the War Department will be able to maintain with the best class of young medical men throughout the land will, it is expected, be of great value in emergency.

It is especially hoped that medical officers of the militia of the various States may be sufficiently interested to secure positions on the Medical Reserve

Corps list.

Officers of the Medical Reserve Corps who may desire to enter the Medical Corps of the army must be between twenty-two and thirty years of age (except in the case of former contract surgeons who entered the service as such before the age of twenty-seven and who were in the service at the time of the passage of the act of April 23, 1908); they must fulfill all requirements for appointment in the Medical Corps that are imposed upon applicants who are not members of the Medical Reserve Corps. Full information in this regard is contained in the circular of information cited above, a copy of which will be furnished upon application.

Official Rems.

Health Reports:

The following cases of smattpax velicus fever, cholera and plague have been reported to the surgeon general United States Public Health and Marine Hospital Service, during the week ending July 3, 1908:

Public Health and Marine Hospital Service:

Official list of changes in the stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the week ending July 1, 1908

CARLTON, C. G., Pharmacist. Granted leave of absence for

thirty days, from August 1, 1908.

DREW, A. D., Acting Assistant Surgeon. Granted leave of absence for thirty days, from July 3, 1908, without pay.
FRIEDMAN, H. M., Acting Assistant Surgeon. Granted leave of absence for twenty-eight days, from July 5,

GASSAWAY, J. M., Surgeon. Directed to proceed to Reedy Island Quarantine Station for special temporary duty, upon completion of which to rejoin his station at Phil-

adelphia, Pa.

Geddings, H. D., Assistant Surgeon General. Directed to proceed to Philadelphia, Pa., and Reedy Island Quarantine station, for special temporary duty, upon completion of which to rejoin his station at Washington, D. C.

Gieson, F. L., Pharmacist. Directed to proceed from Hono-

GISSON, F. L., Pharmacist. Directed to proceed from Honolulu, Hawaii, to Molokai, Hawaii, from time to time, as the exigencies of the service may require.
GOLDBERGER, JOSEPH, Passed Assistant Surgeon. Directed to proceed to Baltimore, Md., for special temporary duty, upon completion of which to rejoin his station at the Hygienic Laboratory, Washington, D. C.; directed to proceed to Alexandria, Va., for special temporary duty, upon completion of which to rejoin his station.

Gray, George E., Acting Assistant Surgeon. Granted leave of absence for five days, from June 22, 1908.

Hobby, W. C., Passed Assistant Surgeon. Relieved from duty on examining board, San Francisco, July 6, 1908.

KING, W. W., Passed Assistant Surgeon. Detailed as recorder of examining board, San Francisco, July 6, 1908.

LAVINDER, C. H., Passed Assistant Surgeon. Leave of absence granted for four days, from June 16, 1908, amended so as to grant leave of absence for three days

OAKLEY, J. H., Passed Assistant Surgeon. Granted leave

of absence for four days

ONUF, B., Acting Assistant Surgeon. Granted leave of absence for two days, from June 20, 1908, on account of sickness.

ROBERTS, Norman, Assistant Surgeon. Granted extension of leave of absence for three days, from July 1, 1908.
SALMON, T. W., Assistant Surgeon. Granted leave of ab-

sence for seven days, from June 28, 1708, under paragraph 101, Service Regulations.

Wertenbaker, C. P., Surgeon. Granted leave of absence for three days, from July 1, 1908.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending July 4, 1908.

BAKER, F. C., Captain. Ordered from Fort Oglethorpe, Ga., to Chickamauga Park. Ga., for duty. CLARK, J. A., Captain. Relieved from further duty at Fort Oglethorpe, Ga., and from temporary duty at Madison Barracks, N. Y., and ordered to proceed on

Madison Barracks, N. Y., and ordered to proceed on August 1st to Fort Liscum, Alaska, for duty.

Grissinger, J. W., Captain. Relieved from duty at Fort Ethan Allen, Vt., and ordered to proceed on August 1st to Fort Egbert, Alaska, for duty.

Hanson, L. H., First Lieutenant. When relieved at Fort Liscum, Alaska, ordered to Seattle, Wash., for orders. Kinkpatrick, T. J., Major. Ordered from Fort Moultrie, S. C., to Chickamauga Park, Ga., for duty.

Lamson, T., Captain. Granted leave of absence for two months, with permission to ask extension of one

months, with permission to ask extension of one month.

Manly, C. J., Captain. Granted leave of absence in the United State from Inly 12 to September 15, 1008.

SCHMITTER, F., Captain. When relieved at Fort Egbert, Alaska, ordered to Seattle, Wash., for orders.

Vose, W. E., Captain. Ordered from Fort Des Moines, Ia., to Fort Mackenzie, Wyo., for duty in the field.

In the A. M. Captain Leit Fort Sam Houston, Lex. or duty at camp, Lean Springs, Lex.

WICKLINE, W. A., Captain. Left Army G. H., San Francisco, Cal., with one half of Company B, H. C., for duty at Leon Springs, Tex.

ZINKE, S. G., Captain. Ordered from Fort Des Moines

Ia., to Fort Mackenzie, Wyo., for duty in the field.

Ia., to Fort Mackenzie, Wyo., for duty in the field. The following medical officers left the General Hospital, Washington, D. C., with fifty men of Company C, H. C., for Chickamauga Park, Ga, Field Hospital No. 8; Captain C. R. Reynolds, First Lieutenant C. D. Cowles, Jr., First Lieutenant E. G. Huber, and First Lieutenant J. S. Lambie, Jr. The following medical officers have been ordered to report at Washington, D. C., on September 21, 1908, for examination for promotion: Majors William C. Borden, W. D. Crosby, G. L. Edie, C. B. Ewing, C. M. Gandy, J. R. Kean, W. D. McCaw, J. L. Phillips, E. A. Mearns. William Stephenson, and M. C. Wyeth.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Navy for the week ending July 4, 1008:

FREEMAN, J. F., Passed Assistant Surgeon. Detached from the navy yard, Boston, Mass., and ordered to the

Montana, when commissioned.

HOEN, W. S., Passed Assistant Surgeon. Detached from the California and ordered to continue treatment at the

Naval Hospital, Mare Island, Cal.

McDonnell, W. N., Passed Assistant Surgeon. Detached from the Severa and ordered to Camp Perry, Ohio, on July 5th, for duty in connection with the Navy Rifle Team.
PAYNE, J. H., Jr., Passed Assistant Surgeon.

from the naval recruiting station, Cleveland, Ohio, and ordered to the navy yard, Boston, Mass., and to addi-

URIE, J. F., Surgeon. Detached from the Pennsylvania and ordered to report before a naval retiring board at the navy yard, Mare Island, Cal., on July 10th, for examination for retirement, and then to the Naval Hospital for treatment. White, E. C., Assistant Surgeon.

recruiting station, Cleveland, Ohio.

Births, Marriages, and Deaths.

BAILEY—PERKINS.—In Woodstock, Vermont. on Tuesday, June 30th, Dr. Walter Channing Bailey, of Boston, and Miss Ruth Perkins.

BURLEY—COCHNANE—In Almont, Michigan, on Monday, June 22d, Dr. J. A. Burley and Miss Myra Cochrane.

LINCOLN—GARWOOD.—In Philadelphia, on Wednesday, June 24th, Dr. George Washington Lincoln and Miss Effie Julia Garwood

Julia Garwood.

Julia Garwood.
Muschlitz—Roper.—In Slatington, Pennsylvania, on Saturday, June 27th, Dr. C. H. Muschlitz, of Philadelphia, and Miss Minnie M. Roper.
NAULTY—ALEEE:—In Perth Amboy, New Jersey, on Wednesday, June 17th. Dr. Charles W. Naulty, of Philadelphia, and Miss Muriel Albee.
Roosa—Bullard.—In Buffalo, on Wednesday, June 24th, Dr. Charles Compton Roosa and Miss Mabel Jennison Paullard.

SACKS—RACOOSIN.—In Washington, D. C., on Sunday, June 14th, Dr. Samuel M. Sacks and Miss Freda Racoosin.

BANKS.-In Livermore, Pennsylvania, on Friday, June

Banks.—In Livermore, Pennsylvania, on Friday, June 26th, Dr. M. R. Banks, aged ninety-five years.
Burnett.—In New York, on Monday, June 29th, Dr. Peter V. Burnett, aged fifty-four years.
Fitch.—In Philadelphia, on Thursday, June 25th, Dr. Pelatiah Fitch, aged sixty-six years.
Lynch.—In Milwaukee, Wisconsin, on Thursday, June 25th, Dr. D. W. Lynch, aged sixty years.
SHADD.—In Washington, D. C., on Wednesday, June 24th, Dr. Furman J. Shadd, aged fifty-five years.
Wilson In Philadelphia Burday June 26th, Dr. William H. Wilson.

THE CÆSAREAN OPERATION: INDICATIONS AND TECHNIOUE.*

By John Osborn Polak, M. S., M. D., Brooklyn, N. Y.,

Obstetrician to the Methodist Episcopal Hoseital: Gynæcelogist the Williamsburgh, Jewish and Deaconess Hospitals.

Cæsarean operation, as now understood, may be either an abdominal or vaginal procedure. dications for the performance of the operation are divided into those which are absolute and those which are relative. The indication is absolute, when the child cannot be born through the natural passages, because of the presence of some pathological condition which admits of no other method of delivery, as in extreme degrees of pelvic contraction, or pelvic deformity, in which the conjugata vera is less than 6.75 cm., or 25% inches; also in high grades of kyphosis, osteomalacia, spondylolisthesis, and Nägele pelves, or where new growths occur in the pelvis, or at the pelvic brim, as osteomata, or where these growths become incarcerated in the bony pelvis, such as fibromata, dermoids, and ovarian cystomata, and obstruct the passage of the head through the birth canal. Cicatricial contraction of the vagina, as also cancer of the cervix and of the rectum, may occasionally result in the formation of such dense and rigid tissues as to make delivery impossible by other than the abdominal route.

The indication for delivery by abdominal section is relative when the operation is put in contrast with some of the intrapelvic methods of delivery, and elected because of its advantages to the mother and the child. The spontaneous birth of an ordinary full term child is impossible when the conjugata vera is less than 7.5 cm., and in view of the excellent results from the modern Cæsarean section done as an elective procedure, before labor or during labor, before the woman is exhausted or infected, I am fully in accord with Williams when he suggests that the upper limit for the relative indication be placed at 8.5 cm. in flat pelves and 9 cm. in the generally contracted pelvis. This places the operation in competition with symphysiotomy or pubiotomy, induction of premature labor, and high forceps, in that class of cases referred to by Milne Murray, where the head does not tend to engage in the brim. Williams lets his patient have the test of labor, particularly if she is a primipara, allowing her a full hour in the second stage; if then there is no engagement and the head cannot be made to enter the brim by

'Read as part of a "Symposium" before Queens Nassau Medica Society, May 23, 1908.

pressure, or tentative traction with the forceps, he elects between the Cæsarean operation and pubiotomy. Such procrastination is, I believe, detrimental to the interests of the mother, as it submits her to a labor in which the bony or other mechanical obstacles are too great to be overcome by the normal expulsive powers, and then requires her to undergo a section when she is already tired out.

Reynolds has shown in his analysis of 289 cases of Cæsarean section by twenty different operators that when the section is performed for purely mechanical indication, its morbidity and mortality are proportionate to the amount of labor which has been endured before the operation. The truth of this observation has been borne home to me many times in my own experience; my patients have convalesced as after a normal labor when the section has been primary and elective, while those patients who have had the test of labor, particularly those who have entered the second stage before the operation was performed, have had a distinct morbidity and much postoperative discomfort.

Certain obstetrical emergencies have been included among the relative indications for abdominal delivery-i. e., eclampsia and placenta prævia centralis. In eclampsia the mass of authority is against the operation, except in the presence of some positive indication, such as contraction of the birth canal. These patients are not good operative risks, standing shock and sepsis badly, and the fœtus is often toxic. The late Lawson Tait and Palmer Dudley performed successful Cæsarean operations for central implantation of the placenta, and became strong advocates of this method of delivery, but when we consider how few viable children are met with in this type of placental displacement, as well as the great improvement made in the manner of controlling hæmorrhage, and of accomplishing the dilation of the cervix, since the introduction of the Pomeroy bag, my inclination would be to adopt intrapelvic methods of delivery rather than to resort to one that is yet comparatively untried.

In an exhaustive paper on primary section in the obstetrically unfit, Reynolds has shown that there is a class of women who are physically unfit to undergo the trial and traumatism of labor by the natural passages, because the expulsive powers are too weak to overcome the normal degree of resistance. This, I think, should include women suffering from endocardial lesions in whom there have been signs

of broken compensation prior to pregnancy.

A further indication of the relative type is when the pelvic outlet is so contracted as to make a forceps delivery impossible, though here the operation comes into competition with embryotomy, also in certain cases already referred to, of an obstructing tumor which becomes incarcerated in the pelvis, as well as in marked displacement of the cervix due to a previous ventrofixation of the uterus. This latter condition has necessitated the operation in forty-one recorded instances. One point needs emphasis, and that is, when section is necessary, it is desirable that it should be determined upon in advance, and be performed as a primary, not a secondary, operation. This necessitates frequent observation of our obstetrical patient during pregnancy, in order that we may estimate the relative size of the child to the pelvis, and the physical strength of the patient.

Vaginal Cæsarean operation has, in my opinion, but a limited indication, notwithstanding Dührssen's enthusiasm—i. e., in primiparous eclamptics, before viability, or before term, with long rigid cervices. In this class of cases vaginal incision will find its widest field, as it affords a prompt surgical means of emptying the uterus without unnecessary trauma.

Technique.—When the operation is determined upon, if elective and time permits, the patient should have the same preparation of her bowels and abdomen as is practised before any abdominal section. If it is an operation of emergency, she should have an enema, be catheterized, and have the skin of the abdomen prepared after she is in position and on the table ready for the operation. This may be done by thorough scrubbing of the abdominal wall, from the mons to the ensiform cartilage, with green soap and warm water, using large hand sponges of gauze as scrubs. The suds are removed with sterile water, and the skin surface is bathed with a I to I,000 bichloride solution in seventy per cent. alcohol. Just before the incision is made tincture of iodine is freely painted over the field of operation, which is protected by a sterile lap sheet placed over the patient. This cleansing of the abdomen is done while the anæsthetic is being given. My choice of anæsthetic is chloroform-oxygen, given with an open Esmarch mask, through which the tube from an oxygen tank is run. Since using this combination I have never noticed anæsthesia of the fœtus, so frequently met with when ether was used, and no efforts to resuscitate the baby have been necessary. A hypodermic of ergotole, 20 minims, is given just as the anæsthetic is begun, or if the uterine contractions have been so violent as to threaten uterine rupture, a sixth of a grain of morphine may be given hypodermically while the preparations for the anæsthesia and the operation are going on.

The instruments necessary for a Cæsarean operation are as follows: Two scalpels, one to incise the abdomen, the other to make the incision into the uterus. Four long hysterectomy forceps, to be used in case it is necessary to do a Cæsareohysterectomy. A pair of heavy, straight scissors, one dozen artery clamps, a needle holder, one dozen long, straight, sharp pointed, Keith needles, and one dozen sharp Hagedom needles. Sterile chromicized catgut No. 2, also one or two tubes of No. 2 plain sterile catgut, or medium braided silk, and sufficient strong silkworm gut to close the abdominal wound. It is well to have the long Keith needles threaded with No. 2 chromic gut, each suture being about twelve inches long, and arranged on a sterile towel before

the operation is begun; by this forethought much delay in suturing the uterus is avoided.

With the patient anæsthetized and on the table, the operator makes the abdominal incision, beginning three inches above and an inch to the right of the umbilicus, and extending it downward to about four inches above the pubes. When the peritonæum is opened, any existing anterior adhesions are freed and the uterus is lifted up by an assistant against the abdominal wound by pressure on the outside of the abdomen, but not eventrated through it, and held in this relation. The operator then takes another sterile knife, and makes a longitudinal incision in the upper anterior surface of the uterus; the wound should be at least five inches long to avoid tearing the myometrium. The uterine wound should be through the thickened upper segment of the organ; one hand is now introduced through the uterine incision, the membranes ruptured, or if there is an anterior implantation of the placenta, the placenta is pushed aside, and the child seized by the feet and withdrawn, while the assistant crowds the uterus well up into and eventrates it through the abdominal wound, as the baby is withdrawn, so as to prevent the escape of liquor amnii and blood into the peritoneal cavity. Soiling of the intestines is prevented by placing a moist sterile towel over the wound back of the uterus. The second hypodermic of ergotole is given at this time, while the placenta and its membranes are being removed manually. Hot sterile salt solution is poured into the uterine cavity, and the uterine suture begun by passing long straight needles armed with No. 2 chromic gut through both sides of the uterine muscle at once. Skipping the mucosa, these sutures are passed at one half inch intervals from below upward, their ends clamped and held by the assistant. The uterus immediately begins to contract as the muscle sutures are introduced; if these do not control the hæmorrhage, the assistant, whose hands are encircling the uterus, may make compression of the broad ligaments, and so arrest the bleeding. This, however, I have seldom found necessary. These sutures are now tied and the ends cut short and buried with a continuous peritoneal suture of fine catgut. organ is then gently massaged and wrapped in hot, moist sterile towels, the abdominal cavity wiped dry of any blood or liquor amnii which may have escaped into it, the omentum is brought down over the intestines, and behind the uterus, and the uterus is dropped back into the peritoneal cavity. The abdominal wound is now closed in layers, peritonæum to peritonæum, with catgut, fascia to fascia, and muscle to muscle, by figure of eight sutures of silkworm gut, thus closing the fat layer without leaving any more absorbable suture material within . the wound. The dressings are applied and held in place with two inch zinc oxide plaster, encircling the body, one of these plaster bands being placed so as to make pressure just above the fundus.

The points of technique which I specially wish to call attention to are: First, that two doses of ergotole are given, one when the anæsthetization is begun, the second as the suture of the uterus is begun. Second, that chloroform-oxygen is the ideal anæsthetic for the child as well as the mother, as it not only does not nareotize the child, but maternally

shortens the narcosis. Third, that control of the hæmorrhage is accomplished by the assistant, who keeps the uterus firmly against the abdominal incision until the child is extracted, and then pushes the uterus through the parietal wound and compresses the broad ligaments until the uterine sutures have sufficiently stimulated the uterus to contract on the uterine sinuses and so secure the hæmostasis. Fourth, that the uterine muscle is closed with chromic catgut instead of silk, and the sutures are introduced through both sides of the uterine incision at once. The observance of these points of detail materially increases the speed of the operation.

In a series of thirteen consecutive and successful Cæsarean operations which I recently reported, my longest time was thirty-five minutes, in a case in which I sterilized the patient by removing both tubes, while my shortest time was sixteen minutes for an ordinary hysterotomy, and the uterine and

abdominal suture.

In closing, let me say that the Cæsarean operation, properly chosen, gives the woman and child equal chances, and deserves a more extended use in the hands of the abdominal surgeon.

DIES CANICULARES.

"Dog Days": "The Physitians Vacation."

By John Knott, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc., Dublin, Ireland.

Who knoweth not, that when the Dogge-starre ariseth, the heate of the Sunne is fiery and burning? the effects of which starre are felt exceeding much vpon the earth. seas at his rising do rage and take on, the wines in sellars are troubled, pooles also and standing waters doe stirre and moue. A wilde beast there is in Ægypt, called *Orix*, which the Ægyptians say doth stand full against the Dogstarre when it riseth, looking wistly vpon it, and testifieth after a sort by sneezing, a kind of worship. As for dogs, no man doubteth verily, but all the time of the canicular daies they are most ready to run mad

Such was the belief, and the teaching, of the laborious and conscientious compiler of the first encyclopædia of science known to the literature of Western Europe: the Natural History of Caius Plinius Secundus (as Englished by that indefatigable "Translator General," Philemon Holland, "Doc-

tor of Physicke").

In the prehistoric centuries, when Chaldwan and Egyptian stargazers laid the foundations of astronomy upon the data of keen and continous observation, furnished through the medium of a cloudless atmosphere and transmitted through untold generations in the keeping of a skilled and privileged hereditary aristocracy, the richly (even riotously) productive imagination of those subtropical and oriental regions did not fail to contribute liberally to the decorative embroidery of the science. A certain proportion of this survived as the formative nucleus of the astrology of succeeding ages; and is distinctly traceable even in the scientific nomenclature of the twentieth century, as well as in the traditional allusions which are so often met with in its general literature. In those remote golden periods of human existence, when our planet formed the fixed centre of a freely mobile and never resting

universe, it was very natural, indeed, that its spherical surface should constitute something of a microcosmic reflection of the latter; as the minutest concentric sphere has-necessarily-at the extremity of its every radius a point which precisely corresponds to that in which the rectilinear continuation of the same intersects the circumference of the outer globe, however large. And as the greater may readily be fancied-especially in the vulgar mind-to influence in every way (as well as to include) the less, the genesis of the idea that all matters terrestrial were originally and ultimately regulated by stellar movements is not after all so very far to seek.

When the facts and opinions based on the sensory observations and associated intellectual reflexions of the homo sapiens of unrecorded antiquity had, to a certain superficial degree of penetration, satisfied his inquiring curiosity regarding the earthy and watery-the respectively solid and fluid-constituents of the surface strata of the world in which he had been permitted to exist, he raised his eyes more frequently to the overarching canopy which he could not (physically) reach, and the intervening and investing atmosphere whose phenomena he could not (mentally) comprehend. The more mysterious and the more remote, the more worthy of worship; and, accordingly, the earliest recorded traces of man's conception and adoration of the divine are distinctly traceable to the sources of light which providence had placed in the heavenly firmament. Abram, the divinely elected progenitor of the chosen priesthood of the human race, came from (arose from) "Ur (light, fire) of the Chaldees," and traveled westward in (and under) the auspicious guidance and protection of the Almighty Father of all, in obedience to the will of Jehovah as he guided him on his earthly pilgrimage. One of the most obvious facts which must have attracted the observation and speculative inquiry of our prehistoric ancestors is the dependence of life and growth on heat (light, fire) and moisture, and the respective central sources thereof; the sun in the heavens above, and the water on the earth beneath. Thus arose the conception of the four original and ultimate elements, earth, water, air, fire, in their naturally stratified arrangement of gravity and levity. And thus, too, was conceived the original idea of the primordial genesis of matters mundane which resulted from the conjunction of the male (superior) parent, cxlum, and the female (inferior) terra. The former overarched—and, as a mere matter of course, governed-the vast underlying and femininely productive field of mother Nature; and in course of time was (for the benefit of the uninitiated vulgar) made incarnate as Jupiter Diespiter. The Son (Sun) of this almighty creative father crossed the bosom of the latter day after day, in his passage from east to west, where he rested from his diurnal labors. His presence was absolutely necessary to life-to existence, reproduction, and growth. With his gradual meridional descent coincided the annual failure of light, heat, vegetative growth, and animal reproductive vigor. After a three days' sojourn in the abysmal darkness of the #000 of the brumal solstice, sol invictus arose again with life and healing on his wings. He was elevated on the ecliptic

cross at the vernal equinox at the sign of aries. "the crucified lamb." And so he was recognized as the friend and savior of not only the human race

but of all animal and vegetable life.

We have the very respectable authority of Lucian of Samosata for the fact that the earliest "dawn of astronomy" descended-with the mysterious Nile -from Ethiopia into Egypt. This latter country being essentially a product of the annual inundation of that unique stream, it is easy to fancy that its inhabitants, whose very existence depended on the regular repetition of that aqueous phenomenon, would watch with the most anxious care every feature of the physiognomy of Nature which might be suspected of exercising even the smallest influence thereon. And through the cloudless atmosphere of that remote territory, on a large portion of the surface of which a drop of rain is rarely, if ever, known to fall, there annually appeared at the exact approach of the summer solstice the longed for vision above the horizon of the most brilliant of all the fixed stars. With a regularity which hardly ever deviated from mathematical precision, the annual swell of the bosom of the Nile proceeded to develop directly after the manifestation of the presence of its celestial herald—the harbinger of life and plenty to the inhabitants of the surrounding country. It is, accordingly, easy to comprehend how the native Egyptians, who appreciated, almost to adoration, the devotion and vigilance of their canine contemporaries, came to associate the idea of the annual appearance of the star in question with the comparably reliable and welcome manifestation of the "watch dog's honest bark."

Those who have had some experience in tracing individual items of the history of etymological research will, however, be prepared to learn without surprise that this origin, and original application, of the epithet of dog star has not been unanimously agreed to. We ascertain from the wealthy lore and stately diction of Sherburne that, according to Arte-

midorus ·

Why it is all'il the Dog Star. The Star Syrius (saies he) is the Cause of Feavers, and therefore by some call'd the Dog, which is a Creature Fierce, and yet fawning, and for that reason πυρέτω ομοίον, resembled to a Feaver.

This derivation is, very evidently, an attempt to bring into evidence the coincident-while contradictory-powers of light and fire, life and death. By corresponding psychological gymnastics, Apollo, as sun god, caused the genesis and diffusion of plagues; and, as medicine god, healed their victims. ready noted, matter was made to consist, in a general way, of four elements: Water (beneath the earth: it was always found there when digged for to a sufficient depth, while its fluidity always enabled it to display its tendency to the lowest attainable level), earth, air, and fire. Accordingly, in the palmy days of the prosperity of the Pythagorean philosophy, the zingues was essentially formed of those constituents arranged in concentric shells in the order so indicated—the rotundity of our planet being recognized. But there was a something else necessary; and the existence of this fifth quiddity, more inexpressibly subtle by far than any of the four element of the group pestulated as a miner, wager The gunder of a community of an improvent;

it played a necessary rôle in the genesis and progress of every physical and vital incident and phenomenon. It penetrated and permeated every interstice of every form af matter, while its presence and influence were essential to every phase of functional activity. It became philosophically familiar afterwards as the Greek $Al\theta\eta\rho$ (ether), and in time became incarnate for the Roman zulgus as one of the avatars of their own supreme Jupiter.

As vain man was placed by his earliest recorded philosophy at the centre of a universe of vastness unthinkable, and as earthly products were obviously influenced by the lights of the overhanging firmament, it is not difficult to conceive how he came to recognize the governing and mediating powers of the "heavenly host." And thus Plutarch, as interpreted to English readers by the illuminating genius of

Philemon Holland:

For the reasons, the blace and the influences of God, which are in Heaven and amongst the Stars, do there continue and remain; but those which be disseminated among the sensible and passible bodies, in the Earth and in the Sea, diffused into the plants and living Creatures, the same dying and being buried, do many times revive and rise again fresh by the means of generations. And hereupon the fable saith thus much more, that Typhon cohabiteth and lyeth with Nephthys, and that Osiris also by stealth and secretly, keepeth company with her: for the corruptive and destroying power, doth principally possesse the extream parts of that matter which they name Nephthys and death: and the generative and preserving vertue, conferreth into it little seed, and the same weak and feeble, as being marred and destroyed by Typhon: unlesse it be so much as Isis gathereth up and saveth, which she also nourisheth and maintaineth.

Such are, of course, the expressions of a profoundly observant and hieroglyphic philosophy, concentrating its parabolic powers on the interpretation of the periodic mysteries of Nature. The Chaldaan shepherd was filled with devotion to the "heavenly host" on whose annual revolutions the growth and increase of his flocks depended-as well as the herbage from which their nutriment was derived. And the Egyptian agriculturist was annually treated to still more cogent and convincing demonstrations of solar and stellar influence. The growth of his cattle and of his vegetables was fairly similar to what was observable in neighboring territories; but the very existence of the soil to which both herb and beast must ultimately look for necessary nutriment depended on the annual tidal rise of a certain stream —which stream was in its turn apparently under the presiding influence of a single fixed star, and that the brightest of all! Easy it is then to the discerning intellect to comprehend the fitness of the perennial inspiration which guided Egyptian wisdom in the production of its wondrous system of natural theology, of which a diluted form was afterwards transplanted into Greece, and graced as it grew with the exquisite symmetry of Hellenic art. Continuing the above quoted reflections, Plutarch proceeds:

But in one word, and to speak more generally, he is still better, as Plato and Aristotle are of opinion: for the natural puissance to engender and to preserve, moveth toward him as to a substance and being: whereas, that force of killing and destroying moveth behind, toward non subsistence; which is the reason, that they call the one lisis, that is to say, a motion animate and wise; as if the word were derived of Feodua, which signifiest to move by a certain science and reason, for a barbarous word it is not. But like as the generall name of all gods and god leases, levil, is derived of air trait fragrants, that is to say,

of visible, and από row θέσντος, that is to say, of running; even so, both we and also the Egyptians, have called the goddesse elois and Isis, of intelligence and motion together. Semblably Plato saith, that in old time, when they said Isia they meant Osia, that is to say, sacred; like as Noesis also & Phronesis, quasi νέφομα, that is to say the stirring & motion of the Understanding, being carried & going forward: & they imposed this word συνείναι, those who have found out and discovered Goodness and Vertue: who have found out and discovered Goodness and vertices but contrariwise, have by reproachful names noted such things as impeach hinder and stay the course of natural things, binding them so, as they can not go forward, to wit, $\kappa\alpha\kappa(i\alpha)$, Vice, $\alpha'\kappa\sigma\rho(i\alpha)$, Indigence, $\delta'\epsilon\iota\lambda(i\alpha)$, Cowardice, and $\delta'\kappa(i\alpha)$, Grief, as if they kept them from $\delta'\kappa(i\alpha)$, or $\delta'\kappa\sigma\rho(i\alpha)$, that it is they kept them from $\delta'\kappa(i\alpha)$, or $\delta'\kappa\sigma\rho(i\alpha)$. that is to say, free progresse and proceeding forward. As for Osiris, a word it is composed of notos and ispos, that is to say, holy and sacred; for he is the common reason or idea, of things above in Heaven, and beneath: of which, our ancients were wont to call the one sort, $i \in \rho \alpha'$; that is to say, sacred; and the other $\delta \delta i \alpha$, that is to say, holy. The reason also which sheweth celestial things, and such as move upward, is called *Anubis*, and otherwhiles *Her*manubis; as if the one were meet for those above, and the other for them beneath; whereupon they sacrificed unto the former a white Cock, & to the other a yellow or of saffron colour; for that they thought those things above, pure simple and shining; but those beneath, mixed of a medly colour.

Such thoughts and illustrations as these exhibit. as I conceive, striking and instructive examples of the inevitable entanglement of the spiritual and the material in this still mysterious universe which exists within and beneath, as well as above and around. that still perplexing entity, the human personality. And very similar ones, indeed, were developed by the Chaldwan star gazer on his alternately scorched. and drenched, and storm swept plain, as well as by the Persian magus on his inspiring mountain summit, to those which occurred to the ancient Egyptian seer as he nightly watched his cloudless horizon for the vision of the joy bearing dog star, which heralded the approach of the annual Nile tide on which depended the collective existence of his nation with the inhabitants thereof. Each saw the continuous struggle which pervaded the whole of the visible universe: above, between light and darkness, day and night, heat and cold; around, between good and evil, pleasure and pain, rest and agitation, health and sickness; and beneath, between gravity and levity, solid and fluid, perpetual water and occasional fire. The philosophic observer of stellar movement, as he sat on the bank of the Nile or of the Euphrates, looked upward with awestruck admiration to the heaven which he could not reach. He looked into the water at his feet and saw all its phenomena reproduced.

Then he turned to the minute sparkling dew drop, and he found there a spherical mirror which actually concentrated beneath its tiny surface a reliably representative, if immeasurably smaller, picture of all the same details. The powers above evidently paid conscious attention to that liquid droplet. Of course, they permeated and regulated his own system! He thus developed the idea of the human microcosm. And the various visible powers which resided in the firmament above received distinctive Thus Plutarch: appellations.

But in the Books of Hermes or Mercury, so called, there is written by report, thus much concerning sacred names, namely, that the power ordained over the circular motion & revolution of the Sun, the Egyptians called Horus, & the Greeks Apollo: that web is over the wind, some name Osiris, others Sarapis, and some again in the Egyptian language Sothi, which signifieth as much as con-

ception or to be with Child: and thereupon it is, that ception or to be with Child: and thereupon it is, this by a little deflection of the name, in the Greek tongue that Canicular or Dog-star is called $K \nu \omega \nu$, which is thought appropriate unto Isis. Well I wot, that we are not to strive as touching names, yet would I rather give place unto the Egyptians about the name Sarapis than Osivis; for this is a most Greek word whereas the other is a strive of the stripe of for this is a meer Greek word, whereas the other is a stranger: but as well the one as the other signifieth the same power of Divinity. And hereto accordeth the Egyptian language; for many times they term Isis by the name of Minerva, which in their tongue signifieth as much, as I am come of myself. And Typhon, as we have already said, is named Seth, Babon, and Smy, which words betoken all, a violent stay and impeachment, a contrariety and a diversion or turning aside another way.

These were, of course, the supreme powers which necessarily received earliest special notice—as most powerfully influencing the life history of man. And the chain of ideas was forged out link by link down through untold centuries on the banks of the Nile, by the members of a royal and hereditary hierarchy. The conditions for the collection and concentration of philosophic wisdom were, perhaps, as nearly perfect as they have ever been in the chequered course of human progress. The unity of the entire cosmos was thoroughly elucidated, and the conception of its representative concentration in the human microcos-

mos was firmly inculcated.

Then, in immediately environing proximity to the person of homo sapiens, there was that mysterious 'element" which so completely evaded the powers of vision, and (in more restricted degrees) those of the various other senses. Its current must freely enter his nostrils in order that the most elementary functions of life may be preserved—the life giving "spirit" was surely in the air, but was the latter wholly of it? Was this agent of animation wholly and absolutely identical with the element whose hurried movements produced the prester and the typhoon? The final answer was slow to come.

There was placed in most remote order the "element" whose manifestations were those of light and Physically it formed the stars; theologically it represented the substance of souls. Thus again

The Priests of Egypt affirm, that the bodies not of these gods only, but also of all others, who have been ingendred, and are not incorruptible, remain among them where they were honored and reverenced; but their Souls became stars, and shine in heaven; and as for that of Isis, it is the same which the Greeks call Cyon, that is to say, the Dog-star, but the Egyptians Sothis: that of Orus is Orion, and that of Typhon, the Bear

There is little difficulty in conceiving how readily spiritual emanations were suggested to the Oriental imagination by observation of the rays of the sun and of the effects of the movements of the invisible The essential and insoluble unity of the universe effectively postulated a great first (originating and continuously governing) cause. And thus we find that in each of the old grandly mystical systems of the Hindus, of the Chaldwans, of the Egyptians, of Zoroaster, of Pythagoras, and of Plato, the anima mundi was an emanation of the ineffable and unknowable Supreme Power, and the anima microcosmi was an offshoot of the anima mundi. rays, genial or scorching, of the illuminating sun, of the moister moon, and of the unnumbered stellar items of the "heavenly host" were all the divine messengers (angels) which descended to earth, and to its theomorphic inhabitant, man.

We also find that humanity, then as now, displayed much gratitude to its deceased benefactors, even when negligent of its living ones:

Now Isis and Osyris for teaching the Egyptians agriculture were after their deaths by them Deified: Osyris adored in the Sunne and Isis in the Moone; because heat and moysture doe procure fertility. Isis is also taken for the land of Egypt, in that so extraordinarily fruitfull: and is said to mourn for the losse of Osyris; that is when the Sunne is in the winter Tropick, the Earth being then disrobed and barren.

Such is the view of Ovid's eminent interpreter, George Sandys, who calls attention to

"that ancient inscription on the Columne of Isis. I am Isis the Queen of Egypt, instructed by Mercury. The lawes which I have made let no man dissolve. I am the wife of Osyris, the Inventresse of Tillage, and mother to Orus. In Heaven I am the refulgent Dog-starre. The city Bubastis was built in my honour. Rejoyce, rejoyce, O Egypt, in that thou hast nourished me."

This learned interpreter of the *Metamorphoses* finds it, of course, necessary to notice, and account for, the association of Isis and the dog with a star of special brilliancy which also displayed unique influences:

Said to be the Dog-starre, in that the Egyptian Astronomers, having the benefit of a plaine countrey, and perpetuall serenity, from their high Pyvamides observed when that starre first appeared before the sun-rising, not eclipsed by his greater light, then being when twelve degrees distant from the Sunne in starres (as this is) of the first magnitude; from thence accounting, untill discovered as before the yeare following. And because the vines and fruits then ripen, the bountifull Nilus begins to flow, and contagious sicknesses to cease, (which in that season in other regions is most outragious) they attributed all these notable benefits to the influence of that starre; and therefore worshipped it under the name of Isis.

And as the priestly seers of the land of the Nile collected, century after century, the results of their continuous observations and reflections on the members —individual, collective, and grouped—of the lights of the nocturnal firmament, they arrived at many curious conclusions. Many were, perhaps, in the view of modern science, very absurd; some were fanciful and poetic; others were exceedingly subtle in their efforts to penetrate the investing cosmic darkness; others still would almost appear to have been inspired-many even profoundly prophetic. Their immeasurable and unbridgeable remoteness of distance; their ineffable loftiness of position; and their (presumably) everlasting and (apparently) spontaneous luminosity conspired to give the heavenly lights a peculiar and inspiring position in the field of human thought. The sun, as "lord of day" and "lord of hosts," and the moon, as "queen of heaven," occupied monarchic positions by day and night, respectively. The "heavenly host" over which they presided was arranged in groups of varied dignity and significance. A foremost degree of importance was attached to those stellar groups within whose limits the sun was always found to perform his yearly revolution. This stellar zone, the Zodiac, was divided into twelve segments; the resulting "constellations" corresponded respectively to the twelve parts into which the period of the sun's "annual" revolution was divided—the portions of time and of space being made to suit by artificial arrangement. The elemental composition of the inaccessible luminaries naturally exercised the speculative curiosity of the natural philosophers. The opinions of the most prominent of that class among the Greeks have been collected by Plutarch. They are as follows (Holland's version):

Thales affirmeth them to be terrestriall, and nathlesse fiery and ardent.

Empedocles holdeth them to be entlained by that tare, which the skie containing within it selfe, do violently send forth at the first excretion. Anaxagoras saith, that the skie which environeth is indeed of the own essence of a fiery nature; but by the vilent revolution of it selfe snatcheth up stones from the earth, and setting them on fire they become Stars.

Diogenes thinketh that Stars be of the substance of a pumish stone, as being the breathing holes of the world; and againe, the same Philosopher saith, that they be certaine blind-stones not apparent; howbeit, falling often to the earth, are there quenched, as it hapneth in a place called αίγος ποταιοί that is to say, Goats rivers, where there fell some time a stone-star in forme of fire.

Empedocles holdeth, that the fixed Stars which wander

Empedocles holdeth, that the fixed Stars which wander not, be fastned to the chrystall skie; but the planets are loose and at liberty.

loose and at liberty.

Plato giveth out that for the most part they be of fire, and yet neverthelesse they participate with other elements

in manner of glue or sodder.

Xenophanes is of opinion, that they consist of clouds inflamed, which notwithstanding are quenched every day, and afterwards againe be fired in the night in manner of coles: as for the rising and setting of Stars, they be nothing else but their catching fire and quenching.

of coies: as for the rising and setting of stratagency mothing else but their catching fire and quenching. Hiraclides and the Pythagoreans hold, that every Star is a world by it selfe, containing an earth, an aire, and a skie, in an infinite cedestiall nature; and these opinions go current in the verses of Orpheus, for they make of every Star a world. Epicurus reproueth none of all this, but holdeth still that old note of his: It may so be.

A somewhat motley array of opinions, the above series forms at first presentation to the critical eve: still, when closely scrutinized in the light of contemporary philosophy and science, the elements of probable or possible incompatibility become almost evanescent. We know from other sources that the sphere of aër reached out to the orbit of the moon, which thus constituted its constringing girdle. Thus came the special significance of the old epithet of sublunar; it applied to the earthly sphere and the contents thereof, and in the more "shady" or de-rogatory sense—as distinguished from celestial. The influence of the evil one and his host of fallen angels was conterminous therewith; in fact, certain heretical doctrinaires of the early centuries of the Christian era maintained the thesis that the rebellious angel of light, when expelled from the presence of the Almighty Father, was permitted to create a world of his own for the permanent future residence of himself and his host of fallen angels. Our planet was the product of that license; and the advocates of this version of terrestrial cosmogony confidently pointed to it as the only possible explanation of the events of daily life and experience in connection with matters moral, social, and political! But on the other side of the moon's surface celestial influences prevailed, and these became more and more divinely pure of essence as the distance from this our terra centralis progressively increased. stance of the heavenly luminaries-sun, moon, and stars-was necessarily the element which afforded light and heat, ignis, fire. Yet those luminous masses were but dense aggregations of the sparsely diffused particles which occupied the vast interstellar spaces. The "Son" [Sun] was "of the same sub-stance with the Father" (Diespater, Jupiter Diespiter), the personification of the utterly indescribable sky (heaven), which was composed of the quintessential Æther.

The inspired speculations of those fanciful and at least semipoetic philosophers of the grand old pagan schools placed "The forme and figure of Stars" in aspects almost as instructive as they did "the substance" of those "angels of the night." learn from the same Plutarch, in the same version,

The Stoicks say, that the Stars be sphearick or round like the world, the sun and moon. Cleanthes holdeth them to be pointed and pyramidall. Anaximenes saith, they stick fast in the chrystalline skie, like a number of nailes. Others imagine, that they be fiery plates, like unto flat

The rays of the sun were rendered distinctly visible when passing through the interstices of an intervening cloud; and the still more delicately subtle ones of the twinkling members of the nocturnal "host of heaven" came in time to be regarded as functional agents in the conveyance of the divine will to the surface of our planet. The stars became the "messengers"—angels—which conveyed to man the words of the remote invisible and ineffable Deity.

The order and arrangement of the celestial luminaries in the limitless regions of space formed a confusing puzzle in the domain of ancient cosmog-According to the system which proved most satisfactory, as well as geometrically neat, the cosmos essentially consisted of twelve concentric spheres, beyond the circumference of the outermost of which was located the immobile empyrean, the eternal abode of the ineffable deity. The central (terrestrial, sublunar) nucleus of this series, which was destined to be the abode of man, included four of those superimposed (concentric) strata: earth, water, air, and fire. Each of the seven planets was set in the wall of a crystalline sphere of immaculate translucency, by the diurnal revolution of which it was carried around its terrestrial centre. A single such crystalline shell was made to function as supporting frame to the whole heavenly host of fixed Manifold were, as might be expected, the heretical modifications of that neatly mathematical arrangement. Plutarch has marshaled a goodly series in illustration of this and other philosophic With regard to "the order and situation Placita. of stars," we ascertain that:

Xenocrates supposeth that the Stars move upon one and the same superficies: but other Stoicks affirme, that there be some afore others in height and depth.

Democritus rangeth the fixed Stars first;

Planets; and after them the Sun, the Moon, and the Day-

star Lucifer.

Plato, after the situation of the fixed Stars, setteth in the first place that which is called Phænon, to wit, the Star of Saturne; in the second, Phaeton, which is the Star of Jupiter; in the third, Pyroeis, that is to say, fiery or ardent, and it is that of Mars; in the fourth Phosphorus, and that is Venus; in the fifth Stilbon, which is Mercury; in the sixth, the Sun; and last, in the seventh, the Moon. Of the Mathematicians some accord with Plato, others place the

Sun in the midst of them all.

Anaximander, Metradorus the Chian, and Crates affirm, that the Sun is placed highest of all, next to him the Moon,

and under him the fixed Stars and the Planets.

By ingenious invention and superposition of cycles and epicycles, the Egyptian astronomy, as expound-'ed by its literally "royal" astronomer, Ptolemy, was made to adapt itself to, and account for, all (or nearly all) the more prominent stellar and meteorological phenomena known to the centuries of the Christian era which preceded the explosive Renaissance. The heavenly motor had by the latter date become quite too perplexingly entangled by its cyclic phenomena, and the engineering skill requisite for its management became progressively harder to attain. So reformation became inevitable: Hieronimo Fracastorio was born in the same year with Martin Luther, and the number of cosmic spheres with whose special localization and gyrational mechanism he was obliged to make himself acquainted, in the course of the acquisition of his unparalleled encyclopædic attainments, amounted to 74! So the machine was bound to fall to pieces-even by its own weight!

It is interesting to notice how the presidential guidance of the times and the seasons and the days and the years was in some instances recognized by the pagan philosophers of classic Greece in tone and language which display a close relationship of thought and diction to those of the Mosaic account. Let us again look upon the page of Plutarch, as viewed through the quaintly tinting prism of Phile-

mon Holland:

Of the signification of Stars, and how commeth Winter and Summer.

Plato saith, that the tokens and significations both of Winter and Summer, proceed from the rising and setting of Sun, Moon, and other Stars, as well fixed as wandring. Anaximenes saith, that none of all this is occasioned by the Moon, but by the Sun only. Eudoxus and Aratus affirm them to be in common, by means of all the Stars: and Aratus sheweth as much in these verses:

"These radiant stars and lights so evident As signs, God hath set in the firmament, Distinct, in great fore-sight, throughout the year, To shew how all the seasons ordered were

And here, in the midst of a critical and, perhaps over much self satisfied generation, I cannot refrain from a moment's contemplation of the unlimited expansion of the divinely revealed cosmogony which is reflected to us from the pages of the Hebrew lawgiver; and the almost similar grasp of universality and correlated unity displayed in the philosophy of Epicurus, as presented to us in the magnificent metres of the Roman Lucretius. The "inspiration" of the "divine" Newton in the domain of celestial mechanics may be said to have limited itself to the solar system; and when that famous scientist deviated through the turnstile of the gateway of chronology he executed a fiasco which has often since procured his followers a temporary detention in the (scientific) doubting castle of the grimly o'ermastering Giant Despair. The theory of Whitehurst confessedly confined itself to the solar system. Burnet, Whiston, Buffon, la Metherie, Baillie, and Kirwan delivered, each in his turn, a cosmogonic message of interpretation (and apology); but limited the same to our own planet and its investing atmosphere. In this special feature, the "father of modern philosophy" offers a very striking contrast to his scientific posterity, and an outline of distinctive resemblance to the poetically inspired philosopher, Lucretius, and the divinely inspired prophet, Moses. Both Epicurus and Descartes adopted the fundamental hypothesis that the initial power of motion was communicated to matter for the grand purpose of creation. Thus endowed, the chaotic mass was allowed, as well as obliged, to enter business on its own account. And so, after the experiences and the

exhibitions of countless ages, the occurrence of all possible-conceivable and inconceivable-junctions and disjunctions, unions and ruptures, decompositions and recombinations, marriages and divorces, we find ourselves in presence of a world so evolved —not yet perhaps to that form of finality calculated to afford supreme satisfaction (the realization of the summum bonum) to the majority of philosophic observers, whether Epicurean or Stoic, Academic or Peripatetic, or-etc. The primordial particles of Epicurus are not all of the same figure; are in no case infinitely divisible; their figures are unchanging and unchangeable; and so the variety of their outlines is the final cause of the variety of texture of the innumerable aspects and forms of compound matter. Then these primordial particles emerge into scientific light again in modern times as the elementary corpuscles of Sir Isaac Newton; and even the nineteenth century corpuscles of (discovered or invented by) Lesage will be found by the trained eye of the expert scientific historian to prevent distinctly recognizable features of their atavistic precession in the course of generative time. And the radiations of to-day are but physically executing the poetica: functions of the primordia minima of Lucretius.

But the elementary matter of Descartes presents the supreme peculiarity of being infinitely divisible. (This was also a distinctive feature of the solitary element 80wp, from which Thales prepared his edition of the zάσμος.) It is also adaptable to circumstance, as evidenced by the fact that its constituent particles, which were all angular at the time of their original endowment with perpetual motion, have, for the most part, at least, long since become perfectly globular by the abrasions produced by ever repeated concussion and friction. And the angular particles detached in those bumping collisions necessarily underwent in their turn a corresponding rounding and smoothing process; thus was produced a series of globular particles of dimensions immeasurably smaller than the original specimens. cordingly, in direct descent from the angular corpuscles of chaotic matter, we have derived three species of material "atoms," globular of a larger size. globular of smaller dimensions, and angular or jagged. The smaller of the spherical corpuscles are, in virtue of their very littleness, gifted with greater activity and passive mobility; and have, accordingly, been used in the formation of the sun and the fixed stars. The larger and, consequently, more quiescent spherules have been spread out to form the ethereal firmament (sky or heaven); while the sedimentary debris of angular or jagged particles were utilized in the creation of the earth, planets, comets, and other meteoric bodies of inferior order.

This primal conception of the creation from an elementary corpuscular chaos was further elaborated for general adaptation by postulating the genesis of sundry and manifold series of perpetual vortices, each in an immense and distinct mass of matter, which owed their origin to the primordial principle of motion with which each was originally endowed. This gyratory movement involved the whole of the mass in each individual case, and thus the origin of such whirl laid the foundation of a distinct and independent planetary system. Every such mass be-

ing composed, too, of the three varieties of corpuscles already enumerated, there resulted in each the formation of specimens of corresponding varieties of orbs; while the vast unemployed series of larger spherules penetrated and permeated each and all. In this fundamental particular, the corpuscular economy of Descartes formed almost an inverted image of that of Epicurus. Each constructed the planet on which he existed from an agglomeration of the jagged and angular, and consequently less mobile and volatile particles. But Epicurus employed his larger globules in the construction of sun, moon, and stars; while he scattered the smaller ones broadcast to make the ethereal atmosphere of interstellar space, and flow with unopposed current through the intercorpuscular interstices of all compound substances and bodies, inorganic and organic; mineral, vegetable, and animal. Each made earth a vortical centre; and the principal difference in the conceptions of the two great cosmogonists lies in the fact that Epicurus really recognized but a single all comprehending vortex, while Descartes had recourse to a process of decentralization (somewhat comparable to the "devolution" of Irish political platforms!) and planted out centres of local government in series of endless array. Such reflections sometimes lead the thinking reader of the twentieth century to wonder how many of the scientific experts of this generation ever remember that the all pervading ether whose presence guides and controls all their subtlest and most mysterious physical phenomena is the Zeus of the philosophic Greek, and the Jupiter of the poetic Roman, of the classic centuries; that they are, in fact, worshiping the same unknown deity—not, of course, "ignorantly," as in the days of Saul of Tarsus. Thus the divine Maro:

Tum pater omnipotens fœcundis imbribus Æther Conjugis in gremium lætæ descendit, who elsewhere sings:

A Jove principium, Musæ: Jovis omnia plena. while his subjacent spouse, and immortal sister, Juno, is the Air ("II pa = uer, by displacement of a single letter) of modern meteorology; facts which clearly account for the thunderings and lightnings of the former, and the frowns and tears and ever changing temper of the latter, divinity.

Let us now turn again to Plutarch to see—with the aid of the spectacles of Philemon Holland—our dog star in another aspect:

... Eupolis, the comicall Poet ... in his comedy named Colaces, that is to say, Flatterers or Parasites, thus saith:

"For why? This rule and precept streightly gave Protagoras. To drinke; that men might have Their lungs well wet and drencht with liquor cleare, Ere that in skie the Dog-star doth appeare."

The torrified atmosphere through which the dog star was wont to make its annual apparition in those southern regions inevitably led to its association with the seasonal development of maximum elevation of temperature. And at the other end of the meteorological pole was manifested its attraction for the life preserving moisture, the supply of which was then so necessary to the preservation of life, both animal and vegetable. We know that some cosmologists were much disposed to reduce the number of actual primordial elements below the four

usually recognized. When Greece had transplanted oriental wisdom into its own productive soil, and began to exhibit Magi of home manufacture, the first of these, Thales, maintained that the primordial form of matter was of one single and undivided element, water (moisture). It did not require excessive ingenuity of reasoning to convince a philosopher of the land of the Nile of the capital importance of this parental constituent of matter. And the characteristic meteorological phenomena of the thirsty season in which the dog star appeared above the horizon undoubtedly led to the growth of the associational idea of the physiological necessity or desirability of deep potations-aqueous, vinous, or mixed-at the approach of, and during, that trying period. The connection is, indeed, sufficient to account for the inspiration of the lines above quoted; and the prevalence of the opinion and the practice is amply testified by the references found in the pages of the classic writers, Roman as well as Greek, in both prose and poetry. But as human nature has, after all, remained radically the same down through all the ringing changes of philosophic theory and physical discovery, we cannot doubt, and surely need not wonder, that the importance of vinous, as well as aqueous, humidity had received ample recognition for untold centuries before the birth of the first of Greece's "wise men."

The importance of the presence of the aqueous element in the process of the decomposition of flesh was too obvious to escape the notice of those early observers, and Plutarch does not fail to preserve an account of a philosophic discussion of the same for the benefit of an inquiring posterity. In an inspiring record of one of the Symposiaques of the intellectual aristocracy of the wisest and most accomplished of existing communities, we learn that:

"I hope, the dog star Sirius, In fiery heat so furious With raies most ardent will them smite And numbers of them dry up quite."

This was fairly in accordance with the teaching of the first of Greece's wise men, who affirmed that all matter was fluid and variable, while the stars were "earthly, yet fiery"; there existed no vacuum anywhere in the cosmos; every specimen of body was divisible in infinitum; and, accordingly, there were no such things as "atoms." And "running to moisture," which was the essential modification of organic matter in the process of decomposition, was after all, but a return to the primordial element from which it had been originally produced, or formed, or created.

And in the same treasury of the philosophic ac-

quisitions of that most interesting age and country, we find, in connection with the discussion of this subject, an allusion which exposes a weak point in the armor of "the most poetical of philosophers," and relieves the modern reader for a passing moment from the depressing burden of the habitual consciousness of his own intellectual inferiority:

It hapned one day in summer time, that one of the company where I was at supper came out with this verse of Alcaus, which every man hath readily in his mouth, and pronounced it with a loud voice:

τεργε πλευμοια- οίνω, το νάρ άστρον περιτλάιετως, that is to say:

"Now drinke and wet thy lungs with winc. For why? the hot dog star doth shine."

No marvell (quoth Nicias) then (a Physician of the City of Nicopolis) if a Poet as Alcæus was were ignorant in that which Plato a great Philosopher knew not: and yet Alcæus in some sort may be borne out in saying so, and relieved in this wise: namely that the lungs being so neere as they are unto the stomack, enjoy the benefit of the liquid drinke, and therefore it was not improperly said, that they be wet and soaked therewith; but this famous Philosopher by expresse words hath left in writing, that our drinke directly passeth for the most part thorow the lungs.

It seems strange, if true, that the great founder of the Academy, who certainly had a fairly approximate (if not absolutely accurate) notion of the (general or "systemic") circulation of the blood, and of the phenomenon of universal attraction, should have actually retained and taught so crudely blundering a version of the very elementary physiological act of deglutition. But the present writer, for one, declines to admit the credibility of the testimony—as superficially interpreted. It is much more probable that the most poetic of philosophers allowed himself loosely to deviate into parabolic or metaphoric expression which might convey such meaning to the uninitiated critical, but was not allowed to deceive the privileged hearers and readers of his esoteric doctrines. The literature of every system of philosophy which has been profoundly and comprehensively elaborated will be found to contain many superficialities of expression and apparently contradictory statements which are read by the profane and the initiated with very wide difference of meaning.

The eternal restlessness of the atoms of ancient philosophy tended in the lapse of ages to their ultimate dissociation from the various corporate masses which they had originally been utilized to create. And thus there necessarily existed throughout all nature a tendency to the same uniform dead level of temperature, and the motion on which temperature depends. Few physicists of the school of Lord Kelvin appear to have dwelt on the fact that their great Caledonian master had been teaching the same lesson in the nineteenth century in different words, when speculating so acutely and profoundly-whether prophetically or unprophetically—on the gradual lowering of the sun's calorific supply, and the general tendency of universal matter to settle down to the quiet of an absolute zero temperature. And how few even of the leaders of the "higher criticism" appear to read, as they run, the fact that as combustion is essentially but a process of decomposition which more rapidly approaches the goal towards which all motion of matter tends, the "general conflagration" with which the Stoics of old wound up the business of their universe, and which reappeared in the Christian apocalypse, was simply another Helenic version of the same story. It was the final stage of the progressive resolution ("devolution") of complex compounds into simpler ones, of the latter into their constituent elements, and of the elements into the one undivided and invisible primordial principle of "ether"—the divine "spirit" which originally moved on the face of the waters.

On examining the cosmogony of P. Ovidius Naso we inevitably find the dog star placed in a position

of special prominence:

Sex ubi, quæ restant luces, Aprilis habebit, In medio cursu tempora veris erunt. Et frustra pecudem quæres Athamantidos Helles, Signaque dant imbres, exoriturque canis.

No contributor to the classical cyclopædic series of sacred lore in the palmiest days of pagan infallibility more fully recognized the dignity of position and cosmic influence of this star than did the apostle of the practice, in all its perfection, of the inspiration which radiated from the person of the ever youthful god of love. And both the poles of its diametrical effect were—as in the case of other celestial powers -fully recognized. The rays of the solar deity promoted growth and life and healing by the genial influence of their warmth; under other conditions they conveyed blight and plague in their intolerable ardor. And so of our dog star; it announced and promoted the inundation of the heavenly gift of the waters of the Nile; it sometimes also blighted the vine and the corn, the annual hope and staff of life of the struggling Italian peasant:

. . . si culmos Titan incalfacit udos Tunc locus est iræ Diva timenda tuæ.

sang the author of the *De Arte Amandi;* and the same ever present consciousness of the irresistible influence of the heavenly bodies upon vegetable growth is to be found reflected in the pages of all classic writers who have referred to the subject. Let us again turn to those of the elder Pliny, who is, as usual, more full in matters of detail than other authorities of pagan antiquity:

The summer Sunstead falleth out alwaies [in Italy] to he just upon the 24 day of Iune, at what time as the Sunne is entred eight degrees within Cancer, as hath bin said before. This is that great point & Tropick of the world: now is the heaven in most force, and the Sun at the highest of his power and vertue. . among those stars that est of his power and vertice.

Trule this season from the Sunstead beforesaid, vnto the setting or occultation of the Harp-star; Casar saith that six daies before the Calends of Iuly; to wit, the 26 of Iune, Orion riseth to the inhabitants of Italy; howsoeuer the star called Orions girdle, appeareth not to the Assyrians before the fourth day of Iuly, vpon which day in Egypt the star Procyon, i. the fore-runner of the Dog-star Syrius, sheweth in the morning, and commeth in very hot and fierie: and sixteen daies before the Calends of August, to wit, the seuenteenth of Iuly, the foresaid star Procyon riseth to them in Assyria. The morrow after, which is the 18 day. them in Assyria. The infortow arter, which is the so all Writers in manner doe agree vpon the rising of that significant and notorious signe, which commonly we call the Dog-star; to wit, when the Sun is entred the first degree of Leo, which falleth out to be the 23 day after the Summer Sun-stead. And in truth both sea and land do find and feele the arrival or comming of this star, yea, and many a wild beast besides, according as we have shewed already in place conuenient. Neither is this starre lesse worshipped and adored than those renowned Planets which carrie the names of gods and goddesses, and haue Divine honours done vnto them. He it is that inflameth and setteth the Sunne on fire: to him is imputed the greatest cause of that extreame hot weather during the canicular daies. . . . This halfe quarter or six weeks space, is that which determineth of vines and vintage, by the meanes of that star which wee called Canicula, the very ruler indeed ouer Vineyards, and whereupon dependent the good or bad season for all our grapes and wine the next yeare. From hence it is, and not otherwise, that the vines are said to be blasted, & the grapes burnt (as it were) to a coale. No haile stormes, no tempest of wind or raine is comparable hereunto, nor doth the like harme to corn and grapes: this causeth many a time scarcitie, and bringeth extream dearth and famine, which neither haile nor tempest doth. As for these tempests, they indomage haply and hurt some fields here and there; but the blast beforesaid plagueth whole countries, far and neare.

The grand old natural philosopher was, of course, thoroughly up to date in his intimacy with the propitatory observances which the very practical pagan theology of his time prescribed for the prevention of those dreaded visitations. Hence were developed the national celebrations of special festivities, and the careful repetition of necessary sacrifices and accompanying ceremonies. The cause of the husbandman's anxiety is fully recognizable:

For mine owne part, I would thinke verily, that the Summer Sunstead ordinarily upon the 25 of Iune is as dangerous; as also the rising of the great Dog-star which alwaies falleth out to be 23 daies after the said sunstead, if so be that the moon doe change in any of these two daies; for then commeth the harm by extremity of heat, which doth so bake and harden the yong kernels of the grapes and Oliues new knit, that they be tanned as it were into a tough callosity, that they can thriue and grow no more from that day forward.

Accordingly, we are prepared to find that a star possessed of so great influence over two of the most important national products received specially prominent recognition in even the liber primus of that divinum ac culestis rationis opus, the Astronomicon of Manilius:

Subsequitur rapido contenta canicula cursu, Quâ nullum terris violentius advenit astrum, Nec gravius cedit. Non horrens frigore surgit, Nec vacuum solis fulgentem deserit orbem. Sic in utrumque movet mundum, et contraria reddit. Hanc qui surgentem, primo cum redditur ortu, Montis ab excelso speculantur vertice Tauri. Eventus frugum verios, et tempora dicunt: Quaque valetudo veniat: concordia quanta. Bella facit pacemque refert, varieque revertens, Sic movet, ut vidit, mundum, vultuque gubernat. Magna fides hoc posse, color cursusque micantis In radios. Vix sole minor, nisi quod procul hærens Frigida cæruleo contorquet lumina vultu. Cætera vincuntur specie; nec clarius astrum Tingitur Oceano, cælumque revisit ab undis.

—thus Englished by Edward Sherburne, Esquire (MDCLXXV):

Next after whom with rapid Motion bent.
(No star than that 'gainst Earth more violent)
The fietee Dog runs; not one for Heat does rise,
Not one for Cold more grievous quits the Skies,
The World afflicting with a different Fate:
Nor ever fails upon the Sun to waite.
Who this from Tawrus Crown first rising see
Ghess thence of Fruits what the Event may be:
What Health, what Quiet may the Year befal:
Here War it makes, there Peace does reinstal:
And as it variously returns doth awe
Th' inferiour World; It's Aspect is their Law.
'Tis strongly credited this owns a Light
And runs a Course not than the Sun's less bright,
But that remov'd from Sight so great a Way
It seems to cast a dim and weaker Ray
All other Stars it foyls, none in the Main
Is drench'd, or brighter thence ascends again.

The interval of twenty-three days between solstice and rising of Sirius is increased to twenty-nine by Varro, and by Columella to thirty. And wider discrepancies are found in connection with the manifestations of the influence of this star; duplex series of which developed by reason of the dating of some from the cosmic ascent, and of others from the heliacal: while others ignored, or were ignorant of, the effect of the precession of the equinoxes.

As the experienced reader would anticipate, there were sundry versions of the terrestrial career of that particular member of the canine tribe whose celestial transmigration and metamorphosis resulted in the formation and location of the dog star. The following is the account given by George Sandys, whose reference to the Egyptian view has been already quoted:

This Icarius was a guest to Bacchus, who gave him a Borachio of wine, and bade him communicate it to others. Certaine shepheards, in his returne into Attica, drinking thereof immoderately, intoxicated fell on the Earth; and imagining that he had poysoned them, slew him with their staves. His dog Nerea by running before and howling, showed Erigone her father where he lay unburied: who after she had interred him, ascended the mountaine Hymettus and there hung her selfe. It is fained that Jupiter, at the intreaty of Bacchus, changed them both into Constellations: calling Erigone, Virgo; one of the six Northerne signes, who carries in her left hand an eare of corne, with a starre of the first magnitude; and her father Bootes; between whose legs shines the eminent Arcturus, which in revenge of his murder ariseth in tempests. But Icarius his dog, which died at the feet of his hanging

Mistris, was called Astricyon, by us the Dog-star: his malignancy as they faigne, proceeding from the former occasion; causing burning fevers, frenzies, and infections: whose reigne determines with the rising of Arcturus; the season then suffering an alteration.

Cicero (de Divinate) bears instructive and interesting testimony to the devoted attention displayed by the Ceans to the annual reappearance of the dog star, and their unlimited faith in its influence and the modes of the manifestation of the same:

Ceos accepimus ortum caniculæ diligenter quotannis servare, conjecturanque capere, ut scribit Pontielus Heraclides, salubrisne an pestilens annus futurus sit; nam si obscurior, quasi caliginosa, stella extiterit, pingue atque concretum esse Cœlum, ut ejus aspiratio gravis, ac pestilens futura sit; sin illustris et perlucida stella apparuit, significari Cœlum esse tenue purumque, et propterea salubre.

The celestial herald of the annual salvation of the land of Egypt became in time known to the Greeks of classical times as χυνός ἀστερισμός and as σείριος. To account for the origin of the latter cognomen, the scholiast of Apollonius cites the testimony of Timosthenes to the effect that it had been the name of the dog-when living here belowwhich had been translated to that position by a special exercise of divine power. We possess the statement of Plutarch to the effect that the ancient Egyptians believed that the constellation in which the star so brilliantly presides had formerly been the soul of Isis. But the divine stage of preexistence is limited by Diodorus Siculus to the single star, Sirius, which figures in ore canis. The testimony of the columnar inscription on the head has already been quoted from the version of Sandys.

The origin of the name acipus has, as might be anticipated, itself given a good deal of trouble to the

astronomical etymologist. It has been derived from σίρειν, to gape; from the fact that the torrid temperature which accompanies its annual preeminence has the effect of compelling dogs to assume that gesture of weariness. It has also been traced to an ancestral σειραίω. to make dry; because its appearance above the horizon was always associated with the parching and cracking of the muddy crust of the subjacent earth: agente terra per caniculam rimas (Virgil in Catalect). Yet again: from 5601 (= @stu)—from its association with torrid climatic phenomena. Still another origin: ἀστεροῦ, i. e., exinanio; quia sudere fluxo nos, exinaniat-according to the authority of the scholiast of Apollonius. Furthermore, from $\Sigma i \rho i s$, an epithet which the Ethiopians had conferred upon the Nile; "as if it were Sydus Niloticum, by reason of the great affinity between Nilus and that Star, for in the Dog days that River hath its greatest Inundation." In that colossal storehouse of learned lore, the Exercitationes Plinianæ of Salmasius, this erudite antagonist of the author of the Paradise Lost remarks that: Stellam porro, quæ in ore canis, Græci σείριων appelarunt a candore, et luciditate flammæ. He points out, too, that the learned grammarians-some of them even Greek-were mistaken in regarding the word as one of Egyptian origin. The name was really of Greek extraction, and he gives references —some of which are quoted below—to its employment by some of the purest Greek writers.

Salmasius embraces—and with apparent pleasure, as might be anticipated from the well known brotherly love of the giants of criticism-the opportunity afforded in this connection of pointing out the confusion of ideas which had developed in the mind of Scaliger anent the nomenclature of Sirius and Canicula: "Græcis σείριως stella in maxilla, vel ore canis. Hanc propriè caniculam appellari Latinis, totam autem μύρφωσως canem notat Scaliger, et fallitur. Nam caniculam etiam Latini vocarunt sidus ipsum, quod Græci κύνος ἄστρον appellant." And he quotes corroborative witnesses. Varro has: "Inde ad caniculæ signum dies viginti novem." And Festus: "Rutilæ canes, ut ait Atejus Capito, canario sacrificio immolantur pro frugibus deprecandæ sævitæ causa sideris caniculæ."

In the progress of his comment on this subject,

Salmasius goes on to observe:

"Græci quoque σείριου pro toto sidere plerunque usurpant. Stellam porro, quæ in ore canis, Græci σείριον appellarunt a candore, et luciditate flammæ,

"HEER deining!

Id est, acutissime splendet, et acutissimi est candoris. . . . Falluntur, qui vertunt, exsiccat, aut incendit. . . . Recte Hyginus: et Sirion appellasse propter flammæ candorem: quod ejusmodi sit, ut præter cæteras lucere videatur.

The word σείριον was used by Æschylus as an epithet of the sun, on account of the brilliancy of its radiations. And from Sophocles we have σειρίων κυνὸς δίκην; while Ibycus applied the epithet to every bright star; "omnia astra ipta vocabat ab eodem candore lucis.'

(To be continued.)

SYPHILIS EXTRAGENITALLY ACQUIRED IN EARLY CHILDHOOD.*

By Frank Crozer Knowles, M. D., Philadelphia,

Assistant Dermatologist to the Philadelphia General Hospital; Dermatologist to the Northern Dispensity, the Church Home for Children, the St. Vincent's Home, etc.

There are no sadder cases in medicine than the innocently acquired chancre, which appears not infrequently in those who have lived the most exemplary of lives. This disease, frequently so loathesome, swoops down on those least suspecting, infection occurring through the most minute abrasion. This subject, although almost worn threadbare, because of the thousands of cases reported, nevertheless should always be borne in mind lest a mistake be made in the diagnosis. What could be worse than in childhood, even in infancy, to be afflicted with syphilis, due to an innocent infection from some accidental source. The various sources of infection are almost too numerous to mention. It has been the aim in this paper to cull out all but the most striking cases of infection, and those occurring, with but a few exceptions, under five years of age. Extragenital chancre is acquired either by direct contact with the secretion of a syphilitic lesion, with the blood, or with the saliva of a luetic patient, and also indirectly from contact with some object containing the same.

Sources of Infection.—The various sources of infection can be classified under several general headings: Parturition, circumcision, vaccination, breast feeding, hand feeding, fondling, household utensils, toilet articles, unsterilized surgical, dental, and electrical appliances, careless and unclean methods in caring for wounds and removal of foreign bodies, and miscellaneous sources.

Parturition.—Although but few cases have been reported of this origin, yet it can be easily seen that contact of the infant's head against mucous patches upon the mother's vulva may produce inoculation. Grünfeld and Weil have each reported a case of this character. In Grünfeld's record a three weeks' old infant was attacked with a chancre on the scalp, followed in six weeks by secondaries. In Weil's case an infant was attacked with a chancre upon the root of the nose, four weeks after its birth. The mother in each case had contracted syphilis late in pregnancy, and the vulva showed numerous mucous patches. In each case also the reporter considered the contact of the head of the infant against the vulva the source of the infection.

Circumcision.—Although circumcision syphilis can scarcely be classed under the title of extragenital, yet it may be mentioned as a prolific source of infection in certain communities. Epidemics have been reported by Segel, Ricord, von Pitha, Hutchinson, and others. Hutchinson describes an interesting series of circumcision chances. The rabbi, who operated on these cases, invariably placed the foreskin, which had been removed, in the same compartment of his operating case. The fresh gauze for the next infant was then placed in the same compartment where the previously removed foreskin had been. A syphilitic infant thus became, because

of the luetic secretions on the fresh gauze, the source of numerous inoculations.

Vaccination.-A great many writers have reported both single cases and epidemics supposedly of this origin. The details in a great many of these are either too indefinite or else insufficient in data to be absolutely sure that vaccination was really the cause. Cases have been reported by Whitehead, Bromière, Morax, Sebastian, and by numerous others. Taylor records a case of vaccinal syphilis, and his diagnosis was concurred in by several other authorities on the subject. Several individuals were successively vaccinated, the same scarifier being used on all without even being cleansed of secretion. The woman vaccinated just before the infant infected was proved to be syphilitic. A chancre appeared upon the right arm of this six months old infant just twenty days after the scarification. The secondaries appeared in six weeks. The largest vaccinal epidemic was known as that of Rivalta, and has been recorded in detail by Cerisse and also by Pacchiotti. This epidemic occurred in the little town of Rivalta, in Italy. An eleven months old boy, suffering from syphilis, was first vaccinated. the surgeon, Cagiola, not noting this condition. This syphilitic child was then used as the vaccinifer for the others. This one source of contagion caused eighty cases of syphilis, consisting of forty-six children, twenty-six mothers and nurses, five husbands, and three brothers and sisters of those infected.

Breast feeding.—The source of infection under this heading has been from large, and also from the most minute lesions of syphilitic origin, on or near the nipple of the nursing woman. Boeck reports two interesting cases in infants. In the first, a child of three months, acquired a chancre on the tongue, from a specific ulcer on the nipple of a wet nurse; in the second, an initial lesion developed on the right side of the frenum of the tongue of an infant boy, from a small luetic fissure on the mother's nipple. Arning has also recorded a case, in which the infant acquired a chancre on the left corner of the mouth from a sore upon the breast of the mother, this latter infant dying from the disease. Some few cases of supposed infection through breast milk have been reported, notably by Cerasi, and also Steinberger.

Hand feeding.—The greatest care should be exercised in the feeding of infants, seeing that all the food and utensils are scrupulously clean. Boeck, Sigmund, Gilbert, Plumbert, and others have recorded cases of infection from hand feeding. Boeck reported a case in which an infant was infected with a chancre of the mouth by a nurse who partially masticated its food for it. In Gilbert's paper a mother and her baby each acquired a chancre of the lip from using the same nursing bottle after a foundling. Sigmund, and also Plumbert, have reported infections from using sugar teats, previously sucked by luetic infants. The former records two infants, each infected with an initial lesion of the lip; in the latter's two cases, a mother was attacked with a chancre upon the right angle of the mouth, while her baby acquired one on the chin.

Fondling.—The fondling of children, chiefly by kissing, has given probably the greatest number of individual cases of extragenital chancre. The

source of infection may be divided into the kissing of parents, relatives, playmates, boarders, strangers, prostitutes, and nurses. Thomas, and also Sterling, have reported an inoculation from the kiss of a The former's case occurred upon the forehead of a two year old boy, while the latter's developed on the lower lip of a boy of six months. In the cases recorded by MacKay, Ryan, and McGuire the mother was the infective source. In the one case, the chancre developed on the right upper evelid in a boy of six years; in another, upon the forehead of a three year old girl; and in a third, on the tonsil of a boy of six years. Solomon and Ivanyi have each reported an example of infection, transmitted by the kiss of an aunt with mucous patches in her mouth. In one case an eight months old infant acquired an initial lesion upon the lower eyelid; in the other, a girl of three, contracted one upon Playmates by their intimate relationship are the communicators of syphilis. A. H. Griffith and Bulkley have each reported a case of this origin. Griffith's patient was a boy of three years, who had been infected upon the upper lip. In Bulkley's case the lip was also the seat of the chancre, in a girl three and one half years old. Fox details an interesting family epidemic from the caress of a boarder. The youngest child, a boy of two years, was first infected with a chancre of the tonsil. He in turn communicated the disease to four other members of the family. Cases of inoculation from the kiss of strangers have been recorded by Despagnet, and by Eltzina. In the former's case, the initial lesion occurred upon the right lower eyelid, in a thirteen months old boy; while in the latter's, the chancre developed upon the last two phalanges of the little finger, of the left hand, in a girl of thirteen months. In Despagnet's case the infant died from the disease. Rollet has recorded the infection of an infant of fifteen months, with a chancre of the lip, a prostitute with mucous patches in her mouth being the inoculator. This infant gave the disease to two sisters, two brothers, and to her grandmother. Nurses by their constant contact with infants have been the source of syphilis. Tchistiakoff and Ivanyi have each detailed examples of this mode of infection. In the former's case, a boy of eight months was inoculated upon the forehead; while the latter recorded two infections, a chancre being acquired on the lip in each case, one patient being a boy of thirteen months, and the other eleven months of age.

Household utensils.—The use of glasses, knives, forks, spoons, etc., in common, has been the not in-frequent origin of lues. Wilson, Roussel, Knowczyuski, and Vidal have each reported either an individual case or an epidemic under this heading. Wilson described an epidemic of five cases in the same family. The baby first acquired an initial lesion of the mouth, from nursing at the breast of The infant also, because of insufficient breast milk, was fed with a spoon. The eldest daughter, eleven years of age, while feeding the haby, tested the heat of the spoon with her lips. She also fed two other children, a girl of seven and a boy of four years, with the same spoon. The three children were attacked with a chancre of the mouth. The mother acquired an initial lesion of the breast from her syphilitic infant. The father and two other

children, who did not use this spoon, remained free from the disease. Roussel has recorded a case, in which a child of seven years acquired a chancre of the right tonsil from using a spoon after her luetic mother. In Knowczyuski's case, a child acquired a chancre of the palate, from using a dessert spoon immediately after an individual with mucous patches in the mouth. Vidal recorded a small epidemic of extragenital chancre in a weaning house. Four children became infected upon the lip after drinking out of the same tin cup from which a syphilitic child had just drunk.

syphilitic child had just drunk. Toilet articles.—These articles of daily use have also added their toll to the long list of those accidentally inoculated. Baxter has described an unusual case, in which a boy of three years contracted a chancre of the tongue from sucking his father's toothbrush. The father was suffering from a recent attack of syphilis and had moist papules upon the tongue. In the case detailed by Pellizari, the infant acquired an initial lesion on the scalp, the source of infection being a comb, which had just been used upon another child who had a pustular

syphilid of the scalp.

Unsterilized surgical, dental, and electrical appliances.-Instruments which have not been thoroughly cleaned have frequently been the cause of a specific infection. Numerous epidemics of vaccinal syphilis have been caused by soiled scarifiers, and might therefore be classed as instrumental. But as these cases have been discussed under vaccinal syphilis, they will not be detailed again under this heading. Secheyron has described an instructive case, in which a child of five years acquired a chancre by the catheterization of the nasal canal. Barclay gives the history of a young girl who had her lip abraded while having a tooth drawn by a dentist. A chancre developed on this site, apparently from infection by the dental instrument. Pellizari reported an unusual case, in which an electric brush was the inoculating medium. The child, who suffered from infantile paralysis, acquired an initial lesion on the leg.

Careless and unclean methods in caring for revounds and the removal of foreign bodies.—Although comparatively few cases have been reported under this heading, yet there are a sufficient number for care to be exercised. Robins has recorded a case, in which a syphilitic uncle was the source of infection by sucking an incised wound, supposedly to promote healing. The primary sclerosis develop-ing upon the dorsal surface of the hand, in a girl of seven years. Björken gives the history of an unusual source of inoculation. A little boy found a discarded mercurial plaster which he placed upon a wound on the back of his hand. A chancre developed on this site. His brother had previously worn the plaster upon a discharging luetic lesion. Kobner has given the details of a case, in which a child of two and one half years acquired an initial lesion between the toes, at the site of a severe intertrigo, infection occurring by using the same water, just bathed in by a syphilitic father, with discharging lesions. Bardinet has given the details of an epidemic from a most unusual procedure. A midwife, with mucous patches in her mouth, formed the habit of rubbing the umbilical cord of each infant she de-

livered with her fingers moistened with saliva; all the infants so treated acquiring initial lesions. As a result of this carelessness fifteen wives, nine husbands, and ten infants were infected. Three of those inoculated died from the disease. Crude methods in treating conjunctivitis and blepharitis have also been the avenue of syphilitic inoculation. Wecker and Baudry have recorded infections from this source. In the former's case, a girl of six years acquired a chancre on the conjunctiva of the right eye, from a mother who cleansed the eyelid with her spittle; of the two cases of the latter, the first was a girl of twenty-five months, who acquired an initial lesion of the eye, caused by the nurse's sister in law rubbing the eye with her finger moistened by saliva; in the second, a boy of four years acquired the lesion upon the lachrymal portion of the left upper eyelid from the mother moistening her finger or a cloth with saliva and then rubbing the child's eye. Two of these children had a conjunctivitis and the other a blepharitis. Szokalski has described a case of infection of a young boy by a syphilitic man, who attempted to remove a foreign body from the eye with his tongue. The boy's chancre originating on the tarsal conjunctiva of the lower eyelid.

Miscellaneous sources .- Six cases reported by Trousseau, Dowse, Taylor, Engelsted, Pontet, and Sigmund have been classed here. Trousseau has detailed the history of a boy, four months of age, who acquired a chancre on the buttock, from contact with mucous patches on the mother's vulva. The child was in the habit of going to sleep with its buttocks against the mother's abdomen. Dowse records the occurrence of an initial lesion of the forearm, at the site of a scratch, in a nine year old girl, from a syphilitic infant. The infant's anus, while being carried, rested on the scratch on the girl's forearm. The infant had numerous condylomata around the anus. The girl was attacked with a malignant ulcerative syphilis, which ended fatally. Taylor has described the history of a girl of ten years, who acquired a chancre of the upper lip from placing the whistle of a conductor between her lips. The conductor boarded in the same house and had mucous patches on the lips and in the mouth. In the case detailed by Engelsted a boy acquired a chancre of the lip from smoking his uncle's discarded cigar stump. The uncle was syphilitic with fissures and moist papules of the mouth. Pontet has recorded an infection of syphilis in an infant of eighteen months, caused by the habit of poking its finger into other people's mouths and then into its own. The source of contagion was a luetic nurse. In Sigmund's case the inoculating agent was the mother's finger, used to cleanse the lips and mouth of her infant. The mother was a midwife with an initial lesion of the finger. baby acquired a chancre on the angle of the lips. It should be stated that in the cases mentioned in this paper, in which infants acquired syphilis from the mother, the mother in each case was attacked with lues either late in pregnancy or after the birth of the child. Therefore no exception to Profeta's law is recorded.

The following case was seen in the skin dispensary of the Children's Hospital:

in two sear of age came to the km dis-

pensary of the Children's Hospital on September 30, 1907. She was plump, bright, and very well formed for her age. The child had had the usual diseases of early life, but with the exception of these had been uninterruptedly healthy. On the first visit, as soon as the child walked in, a raised lesion was noted upon the cheek. The mother stated that the lesion had started on the cheek as a small red sore, on September 3, just four weeks previous to her first visit to the dispensary. The lesion was situated on the left cheek, one half inch to the left of the ala nasi, and just above the left angle of the mouth. It was a dime in size, sharply marginate, raised, densely indurated, inflammatory, and the surface was covered with a yenowish brown sublingual and the submaxillary glands were slightly ensuring of syphilis were present. The surface was covered with a yellowish brown crust. larged, but no other signs of syphilis were present. The patient was carefully examined again on October 4th, patient was carefully examined again on October 4th, the glandular enlargement was noted to be more marked, the anterior and posterior cervical glands could also be palpated, and a faint mottling could be detected on the trunk. On the 9th a faint, brownish, macular eruption could be seen on the trunk, with large pin head sized account of the production of the posterior systems of the predictions. vesicopustular lesions on the posterior surface of the neck A pharyngitis was also present, and the child was pale and peevish. On the 14th mucous patches were noted on the vulva and around the anus; split pea sized, and smaller, flat papules were seen on the neck, inner side of the thighs, and on the lower back. The child had become very anæmic, fretful, and weak. The mother stated that the sleep was disturbed, and the child complained of pains in the body. The specific treatment was not started until dis-tinct secondaries had appeared. To determine the source of infection a careful examination was made of the mother. The mother was found to have a fading macular eruption upon the trunk; mucous patches were also found in the upon the trunk; mucous patches were also round in the mouth. The eruption first developed upon the mother in the early part of July. The source of the child's chancre was thus easily explained. The father's entire cutaneous surface was examined, and also the mouth, but no trace of syphilis could be found. The mother evidently contracted the disease from some outside, unknown, possibly innocent,

In the early part of this paper the transmission of syphilis by means of breast milk and by vaccination has been touched upon. Practically all modern writers agree that uncontaminated breast milk is not an inoculator of lues. The secretions from an insignificant fissure upon the nipple, which might be overlooked, may mix with the breast milk, and thus give rise to the initial lesion. Lee has written an interesting paper which seems to prove conclusively that breast milk is not the communicator of syphilis. In his case a married woman took a strange infant to nurse, giving it one breast and her own child the other. A chancre developed on the breast given to the foundling, but although her own infant continued to nurse at the other breast for six weeks after she developed a syphilitic eruption, it escaped infection. It should be stated that apparently vaccine serum has not been the source of the so called epidemics of vaccinal syphilis. They have apparently been due to uncleansed scarifiers or to the accidental admixture of the blood with the vaccine serum of the infected individual, this mixture of syphilitic blood and vaccine serum then being used for vaccination in the arm to arm method. Foster has written extensively on this subject. In conclusion, the frequency of extragenital chancre in childhood might be mentioned. Fournier, Tarnovsky, Gay, and the Kalinkinsky and Alexandrovsky Infirmaries, have reported seventeen cases of extragenital chancre in children under two and one half years of age, out of 807, or not quite two per cent. Fournier, out of forty-five cases with extragenital lesions, found four, or somewhat less than nine per cent., in children. Kapusun states that in Russia twentythree per cent, of infantile syphilis, from one to ten years of age, is acquired extragenitally. Syphilis extragenitally acquired in early childhood is an uncommon condition, notwithstanding the numerous cases cited in this paper. During the last decade but few cases have been reported under five years

I wish to express my thanks to Dr. Arthur Van Harlingen for the privilege of recording this case, and wish to state that many of these references have been obtained from Bulkley's excellent monograph,

THE MODERN ADMINISTRATION OF GENERAL ANÆSTHESIA IN MOUTH, NOSE, AND PHARYNX SURGERY.

With Special Reference to Pharyngeal Tubage and Laryngeal Intubation.

BY DEWITT STETTEN, M. D., New York,

Assistant Visiting Surgeon to the German Heroita

The satisfactory administration of a general anæsthetic in operations within or about the mouth, nose, or pharynx has been a problem with which, until quite recently, both operator and anæsthetist have struggled with but little hope of a successful The subject is of such practical importance, and the difficulties have been so felicitously overcome that the writer has been induced to emphasize the salient points of the question by this paper, basing his remarks exclusively upon his practical experiences during the past few years, mainly at the German Hospital, New York. He is especially led to do this as the main progress along these lines does not seem to be generally known, for even the most recent textbooks on anæsthesia, including the latest edition (1907) of Hewitt's classical and comprehensive work, refer only to the older methods.

In considering this question it must be borne in mind that the class of operations under discussion can be divided into two distinct subclasses, i. e., operations of short duration and usually of trifling significance, and operations which require a long anæsthesia and are generally extensive and of serious import. It is principally with the latter group that this paper will deal, as the former cases rarely cause either the operator or the anæsthetist much concern. In tonsil or adenoid operations, for instance, a few whiffs of nitrous oxide or ethyl chloride may be given, and the operative work can be performed before the patient recovers consciousness. I no longer use ethyl bromide for this type of cases, as safer and more agreeable anæsthetics are available. Generally an ether, chloroform, or anæsthol anæsthesia, administered until rather deep narcosis is obtained and then discontinued, answers the purpose admirably. The so called Aether Rausch or primary ether narcosis, as first suggested by Packard in 1877 and later advocated by Sudeck in 1901 is popular abroad for these cases. I have occasionally used the Juillard mask for bringing about this condition. As the patients in all these methods rapidly recover consciousness, the position best suited to the operation may be used, and one need not worry about the possible aspiration of blood as the laryngeal reflex is either never abolished or promptly returns after the anæsthesia is stopped.

In larger and more extensive operations the difficulties of the situation are numerous. Aspiration pneumonia has been the bête noir of the surgeon when working about the upper respiratory passages. To prevent the inspiration of blood and mucus is but one of the problems, however. The operator and anæsthetist are in constant conflict, the one ever interfering with the other's work. This, of course, renders a perfect operative technique, an aseptic field, and a quiet uniform, and safe anæsthesia impossible. Various manœuvres were made use of to attempt to overcome these obstacles. Tracheotomy was formerly advocated and the tampon cannula of Trendelenburg, Hahn, or Gerster used. It is now generally conceded that a preliminary opening of the trachea, with its attendant dangers, is an entirely unjustifiable complication except in major operations upon the larvnx itself.

The use of morphine prior to the administration of a light anæsthesia as advocated first by Thiersch for operations about the mouth is of unquestionable service. The patient can be kept in an analgesic condition, suffers little pain, and can frequently assist the operator by phonating, swallowing, expectorating, etc., if necessary. Yet the routine use of morphine is not without disadvantages, aside from the possibility of it being given to patients with an idiosyncrasy toward the drug. Morphine confuses the clear picture of the anæsthesia, particularly so far as the pupillary reflexes are concerned, and I am convinced that many times the respiratory difficulties, which one encounters, such as cyanosis. slow, shallow breathing, and occasional cessation of breathing, are directly traceable to the drug. Further, this interrupted anæsthesia, or as Mikulicz termed it Halbnarkose, with or without morphine, is incompatible with modern surgery. Not only is the essential quiet of the operation and the comfort and ease of the operator decidedly disturbed, but the asepsis is also grossly interfered with. It might also be emphasized that the shock of an extensive resection of a sarcomatous tonsil, for example, is unquestionably increased if the patient is half awake, feels pain, and is struggling during the greater part of the operation. Hæmorrhage is aggravated by the resistance of the semiconscious patient, and the possibility of "fright syncope" must also be considered. That the psychical factor is an important one and that fear can directly produce cardiac paralysis is quite certain, as the interesting cases of Kappeler and Sir Jame. Sumpson show

The use of the Junker apparatus or the more modern Braun and Gwathmey inhalers with oral cannula was a distinct advance, but none permits of a smooth anæsthesia, nor is the aspiration of blood, etc., prevented. The simple attachment of a catheter to these appliances and its passage into the pharynx, as Hewitt suggests, offers the same objections as do the Mason mouth gag or the Hewitt chloroform prop.

Rectal etherization, primarily proposed by Roux and Pirogoff as early as 1847 and revived by Mollière and Yversen in 1884, was shown by many observers, particularly Weir and Bull, to be dangerous and unjustified. The anæsthetic is not under control, and malæna, colitis, stupor with cyanosis. asphyxia, and death may follow its use. Of late this question of rectal anæsthesia, somewhat modified, has been again brought forward in this country by Cunningham and Lakey and Leggett. condensation of ether in the intestine is avoided by keeping it at a temperature of 37° C., and an outlet tube is used to withdraw the vapor if necessary While these modifications may render the method safer than it formerly was, it is still in too experimental a stage for routine practice, and after all it does not do away with the aspiration of blood and its evil consequences.

Various positions of the patient have been tried to obviate the difficulties attending the anæsthetizing and operating on these cases under discussion. The hanging head or Rose posture, the semirecumbent with the head extended, or Payr position, the sitting. Trendelenburg and Kocher, positions all have certain points in their favor, but none overcomes the main obstacles, and all more or less interfere with the operator and his work.

Intubation for anæsthesia scarcely need come into consideration for operations upon the mouth and nose. For pharynx cases it is an important adjuvant to our technical resources, and I shall consider the question more in detail later.

In 1903 Crile proposed a method of administering the anæsthetic in mouth operations which commends itself both for its simplicity and practicability. With some modification I have used this method most successfully in a considerable number of cases and find that it can be applied equally well to nasal and oral operations, except when the nasopharynx or oropharynx is involved. In fact the method was found so useful that its application was extended beyond the scope originally intended for it, and it was used in numerous other head and neck operations, such as mastoid, gôitre, gland, and brain cases, as it enabled one to conduct an anæsthesia often more smoothly than in the ordinary way, and at the same time kept the anæsthetist entirely away from the field of operation. Briefly the plan as originally suggested for mouth cases is a double tubage of the nares into the pharynx, and a packing of the oropharynx with gauze. In nose operations I pass the two tubes through the mouth and pack the oropharynx and nasopharynx. As the success of the method depends mainly upon carefully carried out technical details and the failures one meets with are usually due to lack of attention to these, I shall give an exact description of the plan Technique of Nasal Tubage of the Phorynx.

Fifteen minutes before beginning the anæsthesia the patient is given hypodermatically gr. ½ to gr. 1/6 morphine sulphate combined with gr. 1/200 to gr. 1/150 atrophine sulphate according to age and sex, and provided no idiosyncrasy exists. This combination usually insures a quiet anæsthesia, good respiration, a dry throat, and an avoidance of cardiac inhibition from the anæsthetic or from pharyngeal stimulation. The writer agrees with Schaefer that the preliminary administration of atropine is of decided advantage in every anæsthesia and should be adopted as a routine measure. The patient is then anæsthetized in the usual way with chloroform or a chloroform mixture on an open mask, in order to avoid coughing, salivation and the hypersecretion of mucus which might follow the primary use of ether. When a fairly deep anæsthesia is reached, a Dehnhardt mouth gag is inserted, and the nares and pharynx are cleansed and then swabbed with a four per cent, solution of cocaine in 1 to 5,000 adrenalin chloride. A deep anæsthesia is essential, as the pharyngeal reflex is one of the last to be abolished and the swabbing guarantees a completely anæsthetic state of the pharynx, thorough dryness and the greatest possible patency of the nares. My early failures were all due to carelessness in this matter or to too great haste in introducing the tubes. If the pharynx is not sufficiently anæsthetic the tubes will not be tolerated. They will induce gagging and holding of the breath with an establishment of an actual vicious circle, the cessation of breathing causing the patient to come out of the anæsthesia, and this increasing lightness of the narcosis being responsible for greater irritation on the part of the tubes. Further, secretion of mucus will be stimulated, the tubes will become plugged, the patient will become cyanotic, and the induction of anæsthesia becomes impossible. Should this error have been made it is useless, nay dangerous, to force the anæsthetic. All that can be done is to recognize the mistake, promptly withdraw the tube, induce a deeper anæsthesia with the Esmarch or Schimmelbusch mask, swab the pharynx and try again, although it must be noted that after one failure the irritability of the pharynx seems to be increased and the chances of success on the second attempt are by no means certain. The best way is to carry out the details properly from the beginning, and if this is done the tubes can be easily passed through the nose into the pharvnx and retained.

I have experimented with a number of kinds of tubes and find that a firm walled, soft rubber Nélaton catheter is the most satisfactory. Besides the lateral there should be an end opening, but the tube should have a conical tip, as this facilitates the introduction. Although these catheters can be purchased from the instrument makers one can easily make one by passing a red hot nail through the tip of an ordinary catheter. For adults, Nos. 25 to 27 French is a convenient size. The tube should be well oiled with petrolatum and cautiously passed, with lateral openings downward, horizontally backwards in the inferior meatus until it reaches the posterior pharyngeal wall. One must be careful not to lacerate the nasal or pharyngeal mucosa, as bleeding is undesirable, for the blood will occlude

the tubes and may be inspired. The tube is allowed to pass downwards until the tip is just above the level of the opening of the glottis. The finger is the safest means of determining the correctness of the position. I have made repeated cadaver measurements, including a number on sagittal sections of the head, and find the average distance from the anterior nares to the proper point on the posterior pharyngeal wall just above the glottis to be seventeen centimetres in adults.

After both tubes have been passed, the tongue is transfixed with a silk suture and drawn forwards. Then the posterior part of the mouth and the pharynx is tightly packed with gauze, forming an air chamber between the tubes and larynx. This tampon accomplishes the double purpose of forcing nasal respiration through the tubes, excluding oral breathing, permitting complete control of the anæsthesia, and preventing the aspiration of blood, mucus, and saliva. The two catheters are fixed in position by small plaster strips attached to the face, and if there is any leakage of air, the anterior nares can be further plugged with small cotton tampons. (See Fig. 1.)

Fig. 1.—Nasal tubage of the phatynx for mouth operations (Crife's method), showing the proper position of the tube and tampon.

The tubes are then connected by means of a glass, metal, or hard rubber Y piece tubing. Glass is preferable, permitting of better observation, and the leg should obviously be somewhat larger in diameter than the arms. A convenient length of stiff rubber tubing is attached to this and into the tube is inserted a perforated metal funnel with gauze or cloth cover and a ring for convenient holding. The cut shows the apparatus I have had constructed for this purpose. (See Fig. 2.) It can be easily sterilized. The funnel, as Pedersen correctly suggested, should be held below the level of the head to prevent the anæsthetic running into the larynx. Chloroform or anæsthol is generally used, as they produce the quietest anæsthesia, and with these anæsthetics the depth of the anæsthesia is more quickly regulated. Ether, however, can be used quite as well, especially after the anæsthesia is already induced and running smoothly. Should it be necessary to exclude air the perforations of the funnel can be closed with a plaster strip. Should oxygen be needed, as for instance if cyanosis develops due to the slightly impeded intake of air from the

presence of the tubes, it can be passed through one of the holes in the funnel. One should always remember to avoid ether when the Paquelin is used. I recall an occasion on which I was amæsthetizing a patient for a carcinoma of the tongue operation and not seeing the field of operation was administering ether while the operator amputated the tongue with the cautery. There was a slight leakage of ether vapor through the tampon and this ignited, though fortunately it was quickly extinguished before any damage was done, and the ether withdrawn and chloroform substituted.

F10. c- Apparatus for tubage of the pnarvnx for anæsthesia in mouth or nose operations

If the tubage has been successful, respiration is quiet, and the regular tubular breathing is heard. If the tampon leaks, a whistling is heard or a bubbling is noticed, which is readily controlled by tighter packing. It is manifestly essential that the air chamber between tubes and pharynx be kept closed.

It occasionally happens that one nostril does not admit a tube owing to a deflected sæptum or spur. One tube can then be used, and the other nostril can be plugged, though of course two tubes are preferable, as they permit a larger volume of air, and in case of one becoming accidentally plugged, the other functionates.

Technique of Oral Tubage of the Pharynx.

Though neither Crile nor McHenry, judging from their most recent publications on the subject

(1906), seem to have tried this scheme, it has proved so successful in my hands, in nasal operations, such as extensive plastics for instance, that I deem it

worth the dignity of a separate brief description. After the same preliminaries, except nasal cocainization, the gag is inserted and the tubes, unvaselined, are passed, lateral opening downwards, one on either side of the mouth, along the cheek to the proper point on the posterior pharyngeal wall, just above the glottis. Adhesive plaster is used to fasten them in this position. The tampon is then inserted first behind the soft palate into the nasopharynx, next into the oropharynx over the tubes, and finally between them in the oral cavity. This forces breathing through the tubes and prevents blood from running down from the posterior nares. The tube should be inserted about fourteen centimetres from the teeth. (See Fig. 3.)

the teeth. (See Fig. 3.)

The advantages of these tubage methods are manifold. A quiet. continuous anæsthesia is maintained, and the dosing of the anæsthetic can be accurately gauged. There is no coughing or vomiting to interfere with the operation, and the aspiration of blood, mucus, and saliva is out of the question. Hæmorrhage is readily controlled, the head can be held in the position most suitable for the operation, and the anæsthetist is entirely out of the way of the surgeon and does not interfere with his asepsis.

Another point that I wish to emphasize here is that the nasal tubage itself frequently corrects an imperfect anæsthesia, as it overcomes certain factors which tend to interfere with a quiet narcosis.

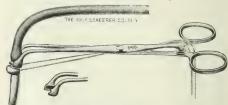

Fig. 4.—Forceps and cannula for intubation on thesia, showing detail of forceps jaw.

I refer especially to the falling back of the base of the tongue against the pharynx. The tube invariably abolishes this form of respiratory obstruction. Recognizing this fact I frequently pass one or two nasal tubes in an ordinary anæsthesia, if this difficulty is met with.

Before leaving this phase of the subject I wish to briefly record the following experience where the introduction of the tubes not only served as a means of administering the anæsthesia but actually prevented asphyxiation and diverted the necessity for a tracheotomy.

Patient, J. B., aged thirty-nine, suffered from a large sar coma of the tonsil which projected into the oropharynx. Anæsthesia was begun with chloroform on an Esmarch mask. When the patient began to relax, sudden deep cyanosis developed, the cause of which was soon found to be the tonsilar tumor, which, owing to the pharyngeal relaxation and enlargement of the growth from the venous engorgement, entirely closed up the oropharynx. Mouth gag and tongue traction being of no avail, the nasal tubes were rapidly introduced. They passed between the tumor and the posterior pharyngeal wall, and the result was an immediate relief of the respiratory obstruction. A long, deep inspiration, as after a tracheotomy, occurred, and then quiet, normal breathing. Color returned, and the operation was performed under tubal anæsthesia, which was continued with perfect smoothness.

Intubation of the Larynx for Anæsthesia.

Laryngeal intubation for the purposes of administering an anæsthetic was probably first suggested by Maydl in 1893, who conceived the idea of attaching a rubber tube to the O'Dwyer cannula, but who leaves us in the dark as to the technical details of introduction, etc. Eisenmenger in the same year used a Schroetter hard rubber laryngeal catheter for this purpose, and O'Dwyer in 1894 indicated that his artificial respiration cannula might be used for narcosis.

Three years later Doyen advocated the use of a special cannula with introducing forceps in nasobuccal operations and to inflate the lungs in opera-

tions upon the chest.

A year later Van Stockum constructed a complicated intubation apparatus for anæsthesia. It consisted of a tube to which was attached an inflatable rubber balloon as in the Trendelenburg tracheal cannula. A rubber tube was attached to the intubation tube, and a special forceps was used for introduction.

Since 1901 the main advocate of intubation anæsthesia has been Kuhn, who had constructed a very elaborate and expensive apparatus for this purpose. He and his pupils, Krug, Floren, and Dirk, have written a large number of papers on the subject, and they advocate the method for practically all operations upon the mouth, nose, and pharynx. Schlechtendahl, Lipburger, and Royce in 1902, and Herzog in 1904 have all favored intubation for general narcosis in mouth operations. They have all used very much the same methods. They intubate in the ordinary O'Dwyer method, and then attach a flexible tube to the intubation cannula.

Though I believe that nasal and oral tubage of the pharynx, as described, entirely do away with the necessity of intubation in ordinary mouth and nose operations, including those upon the palate, it is obvious that in pharyngeal operations, particularly in the removal of large tumors from the nasopharynx, a preliminary intubation for narcosis is the ideal

method.

As the instruments which have hitherto been suggested for this purpose have been either unsatisfactory or difficult to use, or else too elaborate and costly, I have devised a simple tube and forceps which I have tested experimentally upon the cadaver and which has worked most satisfactorily. (See Fig. 4.) It consists of a metal or hard rubber intubation tube constructed on the O'Dwyer principle, but shorter, without obturator, and with carefully rounded inferior extremity. The upper end has a special neck with double collar, the lower for the jaw of the introducing forceps and the upper for the firm, soft rubber tube connecting the intubation cannula with the anæsthesia funnel. The cannula is made in various sizes for different ages. A silk thread through the usual hole makes extraction easy should the rubber tube slip off.

The introducing forceps has the curve of the O'Dwyer introducer, as this is unquestionably the best curve for the purpose. The jaw is so built to firmly grip the lower collar on the neck of the in-

tubation tube.

The tube is introduced after anæsthesia has been induced in the usual way and gauze packing is

placed as needed to make the exclusion of the larynx from the operative field complete. Aspiration is absolutely prevented, and a quiet anæsthesia can be conducted, while the operator works in the pharynx uninterfered with by the anæsthetist. The tube is well borne, nothing more serious than an occasional hoarseness, lasting a day or two, need be feared.

Kuhn, who, as noted before, used his instrument in all mouth, nose, and pharynx cases, also recommends it to overcome laryngeal spasm, straining, and pressing during anæsthesia, particularly in abdominal cases. While I am of the opinion that these disagreeable symptoms can usually be corrected by other means, intubation can be thought of as a last

resort in extreme cases.

The instrument I have described might also be used for the positive pressure method in intrathoracic surgery, which it appears is destined to supplant the more cumbersome and less practical Sauerbruch cabinet. I think that attached to an apparatus such as Greene's it would answer the purpose admirably.

As an additional refinement to technique, a stomach tube might also be introduced. The pharynx could then be tightly packed with impunity, and, should the patient vomit, the stomach could easily empty itself without there being any interference

with the working of the apparatus.

In conclusion I would like to suggest that the present methods of artificial respiration would be greatly improved upon if, when necessary, the patient was rapidly intubated with an instrument like the one described and the rubber tube connected with an artificial respiration bellows, which should be in every operating room.

1356 Madison Avenue.

A CASE OF NEUROGLIOMA GANGLIOCELLULARE OF THE BRAIN: OPERATION: RECOVERY.

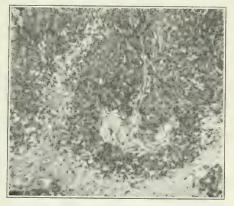

By T. M. T. McKennan, M. D., Pittsburgh, Pa., Neurologist, Allegheny General Hospital. AND F. R. PROESCHER, M. D.,

Pittsburgh, Pa., Pathologist, Allegheny General Hospital.

The patient, a male, thirty-nine years of age, was a butcher by occupation. He had never had any serious illness during his life and had always been strong and

On December 4, 1906, he commenced to have daily head-aches and daily vomiting. Treatment by his physician failed to give any relief. I saw him with his physician, Dr. J. C. McElroy, on March 11, 1907, or about three months after the commencement of symptoms. His symptoms at that time were severe headache, projective vomiting, both paroxysmal and severe, and a marked degree of optic neuritis. There were no motor, special sense, or general sensory disturbances. There was no dizziness and no incoordination. There had been no fever. The intellectual state was clear. He could answer questions correctly. There was a peculiar emotional state. Every few minutes he would break out with uncontrollable laughter and this would only cease when the headaches became severe. The headache seemed to be intense. There was a peculiar glint or stare to the eyes. This, his wife said, was not normal to him, and it tended to make her somewhat afraid of him. I had him removed to the Allegheny General Hospital, where I observed him for a few days. I made up my mind that: 1, There was evidence of a brain tumor; and 2, that this was probably situated in the right frontal lobe

of the brain. My reasons for this opinion were that the pain was most intense on the right side of the forehead, and he localized this pain with his hand, and there was the positive evidence of the emotional condition and the negative evidence of lack of any symptoms pointing to an involvement of the motor area of the parietal, occipital, or temporal lobes, or the base of the brain. (Furthermore, I had in remembrance a case of brain tumor where the patient had localized the pain by his hand. He had mental involvement alone, and I found on post mortem examination a tumor of the frontal lobe just underneath the place where he had localized his pain.) I then determined to

Fic. 1 -Neuroglioma

have performed an exploratory operation over the frontal lobe with the centre of operation over the seat of pain. Dr. O. C. Gaub operated upon the patient on March 14, 1907. He made a large osteoplastic flap and opened the dura. There was no tumor visible, but by the sense of touch Dr. Gaub localized a tumor of the size of a large pecan nut and readily shelled it out. The whole area of brain exposed presented a peculiar yellowish appearance such as I had never seen before. The situation of the tumor was in the second frontal convolution about one and one half inches from the median line.

The patient showed marked shock after the operation, but soon rallied and made an uneventful recovery. He left the hospital in two weeks after the operation. For three months he was apprehensive about himself and had considerable dull headache. He then started to work and has been at work ever since. At this date, May II, 1908, he is well. After operation he did not again exhibit the emotional condition of uncontrollable laughter.

The tumor hardened in formalin, was 2.5 cm. long, 1.5 cm. broad, and 1.8 cm. deep, irregular in outline, grayish white in color, and covered with a very thin, transparent membrane (arachnoidal), thickened at some places. It was fairly hard to the knife in cutting, reminding one of brain tissue, and contained numerous punctate hæmorrhages. The tumor was composed of pale round oval cells, grayish at the borders and rich in protoplasm and with large nuclei, grouped in the form of irregular round or circular groups. Between them could be seen a coarsely fibred, elongated, partly hyaline, partly homogeneous, yellowish mass which was filled with small, round chromatinic cells, most of which contained no protoplasm. These and the mass of cells were highly vascular. Hæmorrhagie foci were also noticed.

The large cell groups, rich in protoplasm under a higher objective, were found in groups or lying thickly together or in isolated positions and were round or oval in shape. Atypical karyokinitic figures were frequent in these cells. The cells wherever they appeared thickly together were of various shapes on account of pressure. They were about the size of normal ganglion cells; a few were twice as large. Occasionally a short, small dendrite was found. Sometimes one of the cells seemed to have two nuclei.

and partly with fine chromatin bodies. The cells for the most part appeared closely together without there being an intracellular substance between them. At some places a homogeneous, pale yellow mass was seen which surrounded three or four cells. Many blood vessels were noticed whose walls were formed almost entirely of a thick layer of round cells, rich in chromatin, similar to glial cells. They were converted in some places to homogeneous mass without nuclei except in the outer layer of cells. We occasionally found between the cell masses more or less curved fibriallary masses; only a few of these fibrillæ seemed to have a membrane. In addition to these cells we found smaller ones of similar morphological characteristics lying closely together, or separated by either a finely fibrillary or homogeneous hyaline substance and interspersed with small cellular masses rich in chromatin.

spersed with small cellular masses rich in chromatin.

The cells did not stain equally, and they showed evidences of necrobiosis where they appeared far from a bloodvessel. The nuclei stained very faintly. The glial cells and fibres seemed predisposed to hyaline degeneration. An hemorrhagic focus contained numerous cells rich in pigment about the size of a large lymphocyte (meta-

morphosed hæmoglobin).

The small cells which were so chromatinic had a very small zone of protoplasm, and the chromatin of the nuclei was in the form of fine granular bodies. Most of the cellular masses rich in chromatin were found embedded in the above described fibrillary and partly also homogeneous cell masses, sometimes thickly, sometimes sparingly. These small cell masses often appeared in rows arranged like a rosary, and extended into the protoplasmic cell masses in this form. No connection between these cells and the fibrillary masses was found, and at some few places where the cells and fibres were not so abundant, swollen fibrillary prolongations were noticed.

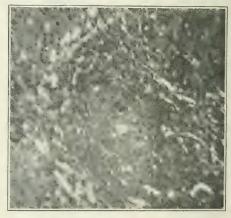

Fig. 2 - Neuroghoma

The microscopical examination therefore revealed a tumor chiefly of ganglion cells, which appeared as closely as the epithelial cells of a carcinoma and were without intercellular substance. Sometimes three or four appeared to be surrounded by a thin capsule similar to what we find with cartilage cells. True axis cylinder prolongations were only occasionally found. Between these ganglionic cells were found normal glia cells which were in places so thick that no glial fibres were found. In other places glial fibres were converted into a homogeneous hyaline mass.

Cellular elements—atypical glial cells—were also noticed They were smaller than the before mentioned ganglionic cells and had a small but distinctly demarcated protoplasmic wall. The nuclei contain small chromatic granules, as cylinder prolongations were absent. They were as thickly interspersed at some places as the ganglionic cells. At other places many glial fibres were found in between. This was not a surprising discovery, for developmentally glial as well as ganglionic cells are derived from the same mother cells. Ganglion cells and glial cells are similar

even in the fully developed nervous system (Kölliker). In such a tumor we can expect to find similar to what is found in the atypical neoplasms, intermediate stages between typical glia cells and ganglion cells.

Fig. 3.-Neuroglioma.

The cellular mass was very vascular. The walls of the bloodvessels were formed directly of neuroglia cells, the cells being arranged in circles. The nerve fibres were mostly nonmedullated, medullated being noticed in a very few places.

Can we regard this tumor as a true neoplasm or as a simple hypertrophy of the brain substance? We believed it to be a true neoplasm, the structure was so different from the brain mass itself. We see here a tumor formed almost entirely of ganglion cells, which were not given time to form cells with fully developed axis cylinders.

We know nothing of the nature of the neuroglioma ganglion cellulare, but it is probably due to misplaced ganglionic cells. Its incomplete development seems to indicate this, also its irregular construction, naked axis cylinders, and ganglion cells without prolongations and bloodvessels whose walls

are formed of glia cells.

Tumors of the central nervous system composed of newly formed ganglion cells and nerve fibres are very rare. In the older literature many tumors are described in which nerve fibres were supposed to be the chief portion. A critical review of these cases shows that only a small portion of the growths were truly composed of nerve elements. Most of them were fibromatous growths, and could only be considered as pseudoneuromata.

We can distinguish, according to location, central and peripheral neuromata. Tumors composed of nerve fibres are called myelinic and amyelinic neuromata, according as to whether they are medullated or nonmedullated. Virchow believed that myelinic neuroma are developed from unmedullated fibres, those which are formed of nerve fibres and ganglion cells are called ganglionic neuroma or neuroma gangliocellulare, or, briefly, neuroglioma.

Pseudoneuromata, which do not interest us here, arise from the endoneural or perineural connective tissue, and are found in the sympathetic as well as

in the spinal and cerebral nerve tracts, and also in the ganglia. It is questionable whether Ranke's neuroma (traumatic type of neuroma, amputation neuroma) can be considered to be a tumor of nerve fibres. In the first type the proportion of nerve substance has been overvalued, as it is very difficult to distinguish nonmedullated nerve fibres from connective tissue bundles. According to Thoma, traumatic neuromata result from a regeneration which extends beyond the physiological limits.

Many writers, therefore, deny that there can be a tumorous growth of nerve fibres. This is the case especially for neuroma of the central nervous system which are said to contain proliferative tumorlike collections of ganglion cells and whose existence is not universally recognized. We must remember that in the various kinds of tumors of the central nervous system (glioma, sarcoma) nerve fibres and ganglion cells are found which are probably remnants of the preexisting nerve tissue. Also developmental disorders of the central nervous system occur in which a transplantation of gray and white matter takes place, the result being an enlargement without us being exactly able to speak of a neoplasm. Not rarely a hyperplasia of normal brain substance occurs which may reach a large volume (corpus striatum). It would be wrong to class this as a neuroma.

On the other hand, we cannot exclude the possibility of transposed nerve tissue becoming the origin of a free neoplasm. We know that some, not all, congenital malformations become the starting points of autonomous cells which may reach an enormous size. The energy which normally is used in keeping the cells to the size necessary for function is freed, and this vegetative growth is the result.

We find in literature a few cases of true neuroma. Virchow and Wagner have described true ganglionic neuroma, originating in the ependyma of the ventricles of the brain, and which contained glia, nerve fibres, and ganglion cells. These were probably of congenital origin. Klebs observed two cases, in one of which the entire spinal cord was surrounded by a mucoid transparent mass which partly entered into the normal nerve substance and which contained many ganglion cells and nonmedulated nerve fibres. In the other there was found a rather sharply circumscribed round growth in the gray matter extending into the white, which also contained numerous ganglion cells and nerve fibres.

That the microscopical picture of a neuroma may be produced, artifically, through traumatism, has been discussed by Van Gieson and Lubarsch. Ziegler described the neuroglioma as a diffuse nodular intermescence of the central nervous system, of a white to gray color, and of slightly harder consistency than the normal nervous tissue, and due to a disturbance of embryonal growth. The glia fibres are mostly of a smooth, shiny appearance; the ganglion cells are of different forms and without dendrites. Neuroglioma have been described which were said to consist only of glia cells and nerve fibres. But the position we take to-day is that such tumors are without significance, as every nerve fibre arises from a ganglion cell, and an isolated neoplasm of nerve fibres is not possible.

BESSEMER BUILDING, SIXTH STREET AND DU-

QUESNE WAY.

A NEW CORSET FOR GASTROPTOSIS.

By Anthony Bassler, M. D., New York,

Visiting Physician to St. Mark's Hospital Clinic.

To relieve the subjective symptoms so that the woman who is suffering from gastroptosis, which, by the way, is not a disease, can digest her food with comfort and can thus take larger meals and become better nourished; to prevent the drag on the lesser omentum caused by the weight of food in a sagging stomach, the musculature of which I believe to be more or less atonic in every case; and to assist in the amelioration of the corporal debilitated neurasthenic picture complex found commonly in these patients, as a therapeutic measure, a support to the abdomen is indicated in all instances, together, of course, with such other important matters as proper dieting, rest, intragastric faradism, tonics and abdominal exercises.

To be helpful to a patient, such a support to the abdominal walls must raise the lower end of the stomach and maintain the organ in this higher level; likewise also the liver, kidney, colon, and small intestine, should they also be low. To do this are used the adhesive plaster bandages of Rose and Rosewater; various kinds of belts, too numerous to mention; and corsets. As each one of these measures presents some advantages over the others a moment might be spent in the consideration of them.

The adhesive plaster belt of Rose's, when properly adjusted, is a valuable appliance. It possesses the advantages of being quickly put on any patient without much preparation or measurement; of being a sort of physiological support; of remaining tight enough to be depended upon for about two weeks; and of being inexpensive. It possesses the disadvantages, however, when continually used, of becoming uncomfortable and irritating to many skins; of the curling over of the edges, so that the face of the plaster adheres to the underclothing; of soon becoming loose from the body, boardlike, and wrinkled, and therefore worthless as a support; and lastly, of the patient being deprived of bathing while the appliance is on. But when a quick relief from the symptoms is desired, for a short time or until a more comfortable support can be made up, it deserves our first consideration. Beyond this its employment is usually not satisfactory.

The objection to most belts that are used is that enough attention to the details of their construction and close fit is not observed. Like with a truss for a hernia, we must not leave these matters to the surgical appliance maker alone, unless he has been specially taught and can be depended upon. The straight transverse belt, however made, only compresses the abdomen. And thus it is that the viscera are pushed directly backward, and then, as the back of the abdominal cavity is resisting, continued pressure raises the viscera. But this is really a long way upward, and in many medium and all thin subjects the x ray examinations show it to be only a fair way at best. Now the object of a belt is not only to support the outside of the abdomen by its circular compression, but it must also serve in the raising of the viscera, that is, it must be a sort of artificial mesentery in ad-

This means the drawing together of the lower front of the abdomen with the waist line in the rear (prolapsed viscera upward as well as backward). Such a belt must be especially constructed with these objects in view (1) and have perineal straps on it to keep it from riding. I agree fully with Pfahler (2) that an x ray examination should be made both before and after the support to the abdomen is adjusted, so as to make sure that it is doing its intended work. It is a practical fact that, unless we are dealing with a patient who has a prominent abdomen sufficient in size so that there is enough bulk to it to give a good purchase to the front of a belt so that a firm draw can be made to raise the viscera, a belt is of little value. In the Landau cases of splanchnotopsia such abdomens are the rule and the belt serves well. But then there are the many other women of thin and medium build, pronounced cases of gastroptosia with subjective symptoms, in whom the best constructed belt is decidedly of less value as a support than the cheapest constructed straight front store corset would be. For the attendant to prescribe the wearing of a belt to such a woman simply induces the conscience of a physician into the belief that he is doing wisely without his taking into consideration the important fact that the belt is going on a flat abdomen which will slip around on the inside of it no matter how tight it may be, and thus it will do no good.

A close observation of this subject in these women has invariably proved that the corset offers the best solution of support, and it may be truthfully said that, while the habit of wearing the waist compressing corset is no doubt responsible for the production or aggravation of many of the cases of ptosis that we see, another corset, specially constructed for the purpose, and not any less fashionable than the first, can be made and comfortably worn to correct it.

Together with the essentials observed by Gallant (3) in the corset he has advanced, that is, "made to order, of fashionable design, gracefully curving in at the waist, and with ample room above the waist line," such a corset should make a deliberate effort to raise and hold up the organs within by a mechanical pressure upon the region of the abdomen bounded by the umbilicus, front points of the ilia, Poupart's ligament, and the pubes; and such a pressure cannot be depended upon as being sufficiently made in slim women by any form of corset that has a flat or convex shaping to the abdomen in this zone. My x ray examinations of the lower border of the stomach with such corsets on have proved this to be the fact beyond the less than half number of women who assert to derive benefit from it. Of course, it must be plainly evident that to any woman who has a large displaceable abdomen such a corset may be quite satisfactory, but it must also be remembered that even in these subjects the pulling up of the mass of soft flabby skin and subcutaneous adipose tissue of the abdomen does not always mean, even if the waist line is materially enlarged thereby, that the internal viscera have also been elevated and are being sustained.

The corset here advanced is particularly for the medium and slight woman, although it can just as well be used for the stout woman. I use it in all

cases of Glénard's disease. Its special feature is that it has a concave abdomen, concaved in its depth according to the extent of prolapse of the organ or organs within and the bulk of the abdomen, otherwise it is a well fitting, stylish, made to order corset, not any larger in the circumference at the waist line than the normal measurement would be, with a contraction transversely to shape it in at the waist, and a corresponding fullness in the costal region to allow for the sustained organs. The concavity is below the umbilicus and at the sides, between that and the anterior superior spines of the ilia down to Poupart's ligament. This feature is brought about by a series of corset steels, which have been bent, then

Author's corset on an extreme case of gastroptosis in a medium sized young woman in whom the corset raised the pyloric portion of her stomach eight cm. with almost immediate relief of the gastric distress after eating, complete relief of constipation, and marked subsequent benefit to her general health.

tempered, and placed in the corset as this illustration shows.

I desire to call particular attention to the fact that, unlike the Gallant corset, the one here described does not depend upon any extreme degree of snug fitting about the hips and lower abdomen to squeeze the underlying tissues and thus hold up the viscera. Even with the women standing the lower part of the corset does not have the extreme close fit as the previously mentioned garment with the women lying down. With my corset the entire hand can be readily slipped between it and the abdomen, and still the support factor is accomplished. Nor is it necessary to loosen the lower string of the corset to put it on, as is necessary in the other garment; the corset when once adjusted is taken off and put on without any widening change, and thus its degree of support is not changing day by day, as is the case when the

strings are constantly being adjusted. Also, in no instance did I find it necessary to pad the lower edge of the corset so as to relieve point pressure on the anterior superior spines of the ilia or elsewhere.

The corset is put on in the following manner, with the patient in the recumbent position: The garment, without loosening the lower strings, is wrapped around the body and the lowest eyelet is fastened in place. The woman now bends her knees, raises her hips from the bed as high as possible, maintains this position for a moment or two before beginning, and then fastens the remainder of the hooks until the corset is closed. This is best done under extreme exhalation. After this the woman is allowed to get up and continue her dressing. Under no conditions must the corset be put on while the patient is in other than the described position, because holding the abdomen up while she is upright with one or two hands is not sufficient to elevate the organs.

Up to the time of this writing twenty-one women have been fitted with this corset, which I may mention can be made by any good corsetière. In all of these has it not only been successful in the way of relieving the subjective symptoms due to the prolapse, but in every instance it has been all that could be asked for in actually and comfortably keeping elevated the lowered organs. And inasmuch as the slim women have always been the most difficult to assist in this way, and as my results have been so gratifying, I advance its use for more general adop-

tion in these cases.

A CASE OF DERMOID TUMOR OF THE CONJUNCTIVA.*

By Marcus J. Levitt, M. D., Brooklyn, N. Y.,

Assistant Surgeon, Mount Sinai Ear, Nose, and Throat Clinic; Chief of Clinic, Eye, Far, and Throat Department, East New York Dispensary, etc.

Dermoid tumors of the conjunctiva are comparatively rare. They are always congenital, benign in nature, and are usually connected with some other malformation or deficient development of the eyelid or other part of the face, such as coloboma or harelip. The usual seat of the tumor is at the sclerocorneal junction, but it may occur at any other place of the conjunctiva. The size varies from that of a split pea to that of a cherry. Histologically, these tumors contain all the elements of skin and its appendages, such as hair follicles, sebaceous and sweat glands. In consistence, they are either hard or soft, according to the amount of fatty tissue they contain.

Dr. Ryba, in 1853, was the first to describe such tumors, calling them dermoids, which name they

*Presented before the Williamsburgh Medical Society N -ember in the 100%

have since retained. According to Van Douyse, dermoids are due to the remains of the amniotic adhesions. Remark describes them as due to the invagination of the ectoderm.

CASE.—S. G., baby, male, five weeks old, was referred to me by Dr. Gingold on June 20, 1907, for some growth of the eye. Mother's age, twenty-one years; father's, twenty-five. History negative. Labor was normal. On examination, the growth measured about 8 or 9 mm. in length, 6 to 7 mm. in width, and 2 to 3 mm. in thickness. It was located at the sclerocorneal junction, more overlapping the cornea. It was somewhat hard in consistence. There was no inflammation and the rest of the eyeball was clear. Four months later the growth was somewhat enlarged, and encroached more on the cornea. The baby was fat, well nourished, and presented no other abnormality. Immediate removal was advised, but the mother preferred to wait until the child grew a little older.

This case is particularly interesting, because the patient has no other abnormity, as is usually found with dermoids; also because it has been under observation almost from birth.

The following cases have been recorded in the

literature since 1865:

RENAL PYURIA WITHOUT APPARENT LESION IN THE KIDNEY.*

By ISAAC LEVIN, M. D., New York.

The parenchyma of the kidneys consists of a conglomeration of a vast mass of urinary tubules and minute bloodvessels, very intimately interwoven. It is very easy for leucocytes to exude from the blood into the tubules and from these to be washed out by the urine. As with other abnormal constituent parts of the urine, leucocytes usually migrate when the epithelial cells of the tubules become diseased. But it is also a priori possible that leucocytes will exude through normal renal epithel

* production to the transfer of the North Andrew North A

ium, in conditions of hyperleucocytosis in the blood, as Talma (1) has recently shown in two cases of renal pyuria due to pyæmia. Consequently, renal pyuria occurs frequently in a great many pathological conditions of the kidney; and the quantity of pus in the urine does not indicate the severity or character of the lesion of the kidney.

We may meet practically normal clear urine in pyonephrosis, where the whole kidney is changed into a pus sac; on the other hand, a great deal of pus may be secreted by a kidney that shows very

little anatomical lesion, if any.

The two cases that I shall report here illustrate this latter condition.

Case I.—Mrs. H., aged forty-eight, came to me in March, 1907, complaining of attacks of pain in the right lumbar region, which had continued for the last six years. At first the attacks occurred once in three to four months; lately they came on every week. Three years ago a diagnosis of kidney stones was made in a Vienna clinic.

The patient was a very robust woman. The lungs and heart were normal. She gave no family history of tuberculosis. On palpation the region of the right kidney was sensitive, but the kidneys could not be felt on account of the great amount of subcutaneous fat. The urine was very turbid, had an acid reaction, contained a great deal of pus and a quantity of albumin corresponding with the amount of pus. Microscopically pus cells and cocci; no blood nor casts. Cystoscopic examination showed normal bladder, pus escaping from the right ureter. Urine drawn from the left ureter was normal.

I considered the case one of a right nephrolithiasis, and made a nephrotomy. At the operation the kidney appeared large and congested; the pelvis was perfectly normal; there was no stone either in the calices, pelvis, or ureter; no abscess anywhere. The kidney was closed with deep sutures. The patient made an uneventful recovery, and has had no attack of pain since the operation, the urine re-

maining free from pus.

The second case gave a different clinical picture.

CASE II.—Mrs. J., aged twenty-nine, suffered from pul-monary tuberculosis in 1903, which became quiescent. Three months previous to the last illness she had an interval appendectomy done. On May 28, 1907, the patient had a sudden chill with severe pain in the right lumbar region. When I saw her the temperature was 104° F., pulse 124, tongue coated. The right kidney could be palpated two fingers below the border of the ribs; it was large and painful to the touch. The urine was turbid; full of pus; reaction acid. Microscopically pus cells and cocci; no tubercle bacilli, no blood, nor casts. For ten days the patient was kept in bed and treated internally without any change in her general condition, the temperature ranging between 101° and 105° F. The quantity of pus in the urine did not diminish. I then made a cystoscopic examination The bladder appeared normal; pus was excreted by the right ureter; urine drawn from the left ureter was normal. Under the impression that I had here to deal with a pyonephrosis, probably of tuberculous origin. I performed a right nephrotomy. right nephrotomy.

At the operation the kidney appeared large and congested. There was no suppuration anywhere in the cortex or pelvis; no tubercles. The kidney was closed with deep sutures. The temperature became normal on the next day. In ten days the urine was clear of pus, and has remained

normal since.

Neither of these cases can be considered, in my opinion, as simple catarrhal pvelitis. In the first place, with the severe condition of the patients clinically and the great amount of pus in the urine. there should have been found some lesion on the walls of the pelvis. Furthermore, at the operation the kidneys were incised and then immediately closed, without draining the pelvis, and still the pyuria ceased imediately.

The first case resembles most the cases of

nephritis accompanied by renal colics and hæmaturia as described by J. Israel (2), which he cured by nephrotomy. The only difference is that in the case described here there was no blood, but pus in the urine. That leucocytes may appear in the urine in Bright's disease, Schnütgen (3) has shown in his analysis of a number of cases from Senator's clinic. Talma reports two cases of renal pyuria, where, at the autopsy, the kidney was otherwise perfectly normal, and only microscopically the canals were filled with leucocytes. Von Jaksch (4) also describes two cases of pyuria in tuberculous patients where, at the autopsy, no lesion was found in the urinary organs. Guyon (5) asserts that tuberculous patients occasionally suffer from pyuria without any lesion in the urinary organs, "pisseurs de pus" he calls them.

The second case, while clinically resembling very closely an acute attack of pyelitis, presented at the operation a perfectly normal pelvis. Furthermore, it was certainly not a case of an ascending pyelitis, and since the pyogenic infection was travelling through the bloodvessels of the cortex of the kidney, it is natural to suppose that the bacilli invaded the whole body of the kidney and caused a general intoxication of the organism, without producing a

localized lesion in the kidney. In my estimation, these cases seem to indicate again that nephritis may be unilateral and present a clinical picture of a surgical disease of the kidneys, and then be amenable to surgical treatment. It may be well to consider in this connection whether, in cases of renal pyuria with uncertain ætiology, that do not respond to medical or dietetic treatment, it would not be proper to wash the renal pelvis before proceeding with operative interference. In my opinion, lumbar incision and inspection of the kidney is hardly a more dangerous undertaking to the patient than a pelvic lavage. On the other hand, we know that there is not another field of surgery where the operator meets with more surprises than in an exploratory incision of the kidney. The biggest stone I ever extracted from a kidney, weighing forty-two grammes, was from a patient with a floating kidney, who had suffered apparently only from general neurasthenia and some vague discomfort in her right side. The examination of the urine showed no abnormality. The house physician and myself were under the impression that a great many of her nervous symptoms were due to the floating kidney, and after eight months of medical treatment and the use of an elastic abdominal binder, we de cided to anchor the kidney, with the result that stones were found.

Consequently, unless it seems absolutely certain that the renal pyuria is due to catarrhal pyelitis, without any involvement of the kidney, nephrotomy is a better procedure than pelvic lavage.

Correspondence.

LETTER FROM LONDON.

The Research Defense Society.—The Sculptures on the British Medical Association's New building. The New New Nurses' Registration Bill.—The Franco-British Exhibition.—A New List of Honors to Medical Men.—Sir Henry Pilman's Hundredth Birthday.—The Late Dr. Bertram Abrahams.

LONDON, June 30, 1908.

The first meeting of the Research Defense Society took place on June 19th, Lord Cromer, the president, being in the chair. Mr. Stephen Paget, the honorary secretary, stated that there were now 1,290 members, and the number was rapidly increasing. They had already issued a series of pamphlets and leaflets, and these included a short account of all experiments on animals made in Great Britain during 1906, a pamphlet by Dr. Courtauld on the value of antitoxine in the treatment of diphtheria, and a reprint of Dr. Osler's evidence before the Royal Commission on the relation of experiments on animals to the prevention of malaria and yellow fever. The committee had also published a monograph by Colonel David Bruce on the extinction of Malta fever. The committee had decided that the society ought to be incorporated under the Companies Liability Act. In conclusion, the report stated that applications for membership had been received, not only from all parts of the United Kingdom, but from America, Canada, India, and Egypt. There was reason to believe that the example of the society would be followed in America, and that an American society would act in association with that of Great Britain. Lord Cromer then delivered the presidential address. He stated that when he was invited to become president of the society he was surprised, as, not having any special scientific knowledge, he considered himself unfit for the post of president. But it was pointed out to him that this absence of specialized scientific knowledge was an advantage. The men of science wished to show that they had the support of those who could lay no claim to special scientific knowledge. Lord Cromer then eloquently and forcibly gave a defense of vivisection. He had received many letters and communications from antivivisectionists, couched in violent and unreasonable language, but he respected their motives, and would reply to them in no unfriendly spirit. He then went on to show that, from his own experience, he had seen malarial fever almost entirely disappear from the town of Ismailia and the Suez Canal. Had it not been for experiments on animals, the cause of malaria could never have been discovered. He also dealt with rabies and diphtheria, pointing out how in each case experiments on animals had led to results which benefited humanity.

Sir Thomas Barlow then proposed the first resolution, that the Research Defense Society be constituted to make known the value of animal experiments to mankind. He laid stress on the determination of the society to put before the public the whole facts of experimentation on animals and its results, which had been so persistently misrepresented and

distorted.

Lord Robert Cecil, in seconding the resolution, made a most effective speech. On being put to the meeting, the resolution was carried unanimously. Mr. Walter Long then proposed the second resolution, that it should be among the objects of the society to establish branch societies and to take such steps as the committee might, from time to time, think advisable in the interests of science. He referred to the work of stamping out rabies in this country, in which he took so prominent a part, and said that the Government would never have embarked on that enterprise had it not been justified by the knowledge of scientific experts on whose advice it was able to rely.

Dr. C. J. Martin, in seconding the resolution, made a good point when he stated that the progress in the study of cancer was not realized by the public, and he observed that it was not generally known that one out of every eight women or eleven men who reached the age of thirty-five years was, according to the registrar general's return for 1905 and 1906, fated to die from cancer. This resolution was also carried unanimously. Altogether, it was a most successful meeting, and the result speaks well for the success of its future work.

The new buildings of the British Medical Association, in the Strand, are just being completed, and the boardings in front of the building taken down. Several fine statues are exposed in front of the building, and one or two of the London newspapers have been regaling their readers with lurid accounts of indecent statues exposed in public. The eager public has crowded in the Strand as a consequence to gaze on the statues. As a matter of fact, the statues are placed so high up that it is difficult for any one in the street to see them plainly, but, now that attention has been drawn to them by the papers, some of the spectators have come with opera and field glasses to gaze on the spectacle.

Among the medical profession, Mr. Edmund Owen has objected to them as being indecent, and for a time the boardings in front were replaced to hide the statues from view. The Times and other better class newspapers, however, defend the statues, which are also highly praised by architects and artists, including the Slade professor of art of Oxford University. The subject was carefully considered by the building committee of the British Medical Association, and they have recommended the Council to leave the statues as they are. Probably the whole matter is the result of a cleverly engineered scheme of the sensational newspapers to give their readers some spicy copy. The Council

are wise not to take any notice of it.

A new bill has been brought into the House of Lords by Lord Ampthill, to deal with the question of registration of nurses. It provides for the incorporation of a general council of nursing education and registration for the United Kingdom, to be constituted as follows: Three persons appointed by the Privy Council to represent the training schools for nurses in the three kingdoms, five registered medical practitioners appointed by the various medical organizations, and ten registered nurses elected as direct representatives of the registered nurses of

the United Kingdom. Members will hold office for

The duties and powers of the council are to publish annually a register of trained nurses, with their qualifications; to appoint examiners and inspectors; and to issue and cancel certificates. For existing nurses the requirements for registration are that the applicant must be at least twenty-one years of age and of good character, and must either hold a three years' certificate of training from an approved general hospital or poor law infirmary, or produce satisfactory evidence of training, and have been for at least three years in bona fide practice. The examination and registration fees are not to exceed five guineas. This is a comprehensive measure, but it has not much chance of becoming law during the present session of Parliament.

The Franco-British Exhibition is now approaching completion, and the aspect presented by its interior is magnificent. The buildings are all painted white and beautifully decorated, and are arranged as a series of courts with central gardens. The arts and sciences are well represented, including French, English, and colonial exhibits. Most of the scientific institutions of Great Britain and France are represented, including an interesting exhibit by the

Pasteur Institute.

The Honors List in connection with the King's birthday was issued last Friday, and the medical profession are well represented. Among the baronets are the names of Sir Thomas Lauder Brunton, M. D., F. R. C. P., F. R. S., and William Watson Cheyne, C. B., F. R. C. S., F. R. S. Knighthood has been conferred on Colonel David Bruce, C. B., F. R. S., and Robert William Burnet, M. D. Sir Lauder Brunton is sixty-four years of age, and was knighted in 1900. His name is well known to all medical men. Mr. Watson Cheyne is one of the best known surgeons in England. He acted as consulting surgeon to the British forces in the South African campaign, for which he was made C. B. Colonel David Bruce has distinguished himself in bacteriological work, especially in connection with Malta fever. Dr. R. W. Burnet was the medical attendant as well as the friend of the late Prime Minister, Sir Henry Campbell-Bannerman, although his title to recognition does not rest by any means on that circumstance alone.

To-morrow, July 1st, Sir Henry Pitman, M. D., will celebrate his hundredth birthday. Sir Henry is consulting physician to St. George's Hospital, and was one of the first graduates of London University. It is probable that he is the dean of the medical

profession in this country.

I regret to announce the death of Dr. Bertram Abrahams, senior assistant physician to the Westminster Hospital, at the early age of thirty-eight. In addition to being assistant physician he was lecturer on medicine and subdean. He was elected a fellow of the Royal College of Physicians in 1904. He was recently appointed medical inspector of schools to the London County Council. In 1907 he delivered the Arris and Gale lectures before the Royal College of Surgeons. He was the author of several medical works, and edited a German-English dictionary of medical terms.

Therapeutical Aotes.

Formaldehyde Against the Bites of Insects.—According to Joly (*Presse médicale*), the following mixture is useful to allay the irritation caused by the bites of mosquitoes and similar insects. The parts bitten should be lightly touched with the solution by means of the glass stopper of the container:

| P_{i} | Formal | | | | | | | | | | | | | | | | | |
|---------|--------|--------|------|-----|------|------|--|--|------|--|---|--|--|---|----|----|---|---|
| | Acetic | | | | | | | | | | | | | | | | | |
| | Xylol, | | | | | | | | | | | | | | | | | |
| | Canada | turpe | ntii | ıe, | | | | | | | ٠ | | | g | Γ. | X | V | , |
| | Oil of | star a | nis | e, | | | | | | | | | | | | q. | S | |
| M. | | | | | | | | | | | | | | | | | | |

The Egyptian Treatment of Uncinariasis.— This method of treatment is described by Albert G. McGill, in *The Journal of the Arkansas Medical Society* for May 15, 1908, as follows:

After having administered a preliminary purgative to clear out the canal, give the following:

| \mathbf{R} | Oil of eucalyptus, | | |
|--------------|---------------------|------|--|
| | Spirit of chlorofor | | |
| M. | Castor oil, | | |
| TATE | | | |

This mixture is divided into two or three doses, and a dose is given every two or three hours, the whole to be followed by a saline purgative.

The Intravenous Administration of Strophanthin.—The Medical Chronicle for July, 1908, cites an article by C. Höpffner, in the Deutsches Archiv für klinische Medizin (1908, 92, p. 485), reviewing the results in a series of cases in which strophanthin was administered intravenously. Höpffner has treated thirty-four patients, giving seventy-eight injections in all. He recommends the dose of one milligramme (1/64 grain), which may be repeated in not less than twenty-four hours. One of his cases, a patient with chronic nephritis and heart failure, received and profited by eleven such doses in six weeks. The treatment is said to be indicated in severe cases of heart failure that will not react to digitalis, or in patients where an immediate effect upon the heart is desired, and strophanthin is employed to pave the way for digitalis, or thirdly, in cases of chronic nephritis with heart failure. No unpleasant symptoms follow these intravenous injections, now that the drug is supplied and administered sterile.

Another report on the use of strophanthin administered intravenously in cardiac lesions by Dr. F. Lust is also reviewed in the number of the Medical Chronicle previously cited. After a reference to the papers of other writers, Lust describes his own experience of the method, saying he had been highly impressed with its merits and the good and speedy effects it had upon the failing heart. The strophanthin is supplied in sterilized solution; the dose is one third to one milligramme (approximately 1/192 grain to 1/64 grain); the intravenous injections should not be given more often than once in twentyfour hours. Their good effect in slowing, regularizing, and strengthening the cardiac contractions appears in a few minutes; the respirations become less rapid, and the secretion of urine is much accelerated within a few hours' time. The number of

injections that it is advisable to give in any given case depends upon the way in which the patient reacts to the drug. If no improvement is seen after two or three doses, treatment with digitalis, theocin, diuretin, or some other diuretic may well be begun; most cases of heart failure with œdema, however, react well to strophanthin. Lust gives details, pulse tracings, and tables showing the good effects of the intravenous injection of the glucoside in a number of patients with heart disease. He also notes that there are cases of failure of the cardiac muscle in which all drugs seem powerless, and he is as vet doubtful whether strophanthin can be employed with success to ward off heart failure in lobar pneumonia. He has only once seen any ill effects follow its employment, due attention being paid to the fact that it exerts a cumulative action. If there is much arteriosclerosis, the dose should be one third to one half milligramme, that is, 0.30 to 0.50 c.c. of the solution in which the drug is supplied.

Caustic Paste for Old Ulcers.—Felix (Gasette médicale de Paris, June 15, 1908) is the author of an interesting note on the treatment of the old and rebellious ulcers (rodent ulcer, varicose, indurated, and syphilitic ulcers, etc.), which occupy so much of the surgeon's time and attention. Positive results have been obtained in the treatment of these cutaneous lesions by means of the rational use of x rays and radioactivity, especially of radium bromide, yet it is not always possible to apply these agents, their use being denied for obvious reasons to practitioners in remote country districts. It is for the benefit of such that Dr. Felix describes his method of cauterization by means of a paste composed of substances that are respectively caustic, antiseptic, anæsthetic, hæmostatic, and modifiers of tissue. The formula for his paste is as follows:

| P. | Wheat flour, |
|----|------------------------------|
| | Starch, Siss; |
| | Corrosive sublimate, gr. xv; |
| | Thymol iodide,gr. xv; |
| | Cocaine,gr. xv; |
| | Monobromated camphor, |
| | Carbolic acid, crystals, |
| | Zinc chloride, dry, |

Mix the ingredients in a glass or porcelain mortar, having previously reduced each drug separately to a state of fine powder. When all are sufficiently mixed add in small quantities at a time enough distilled water to make a homogeneous paste free from gritty particles or lumps. The paste is made more ductile and malleable by the addition of a small amount of glycerin.

Formula for a Sulphur Bath.—To prepare a sulphur bath, order to be dissolved in a large sized bath tub of water the following mixed powder:

| R | Sodium | sulphide, | , | | | | | | ٠ | | | | | | | . 3 | i ; | |
|----|--------|------------|---|--|--|--|--|--|---|--|--|--|--|--|--|-----|-----|--|
| | Sodium | chloride, | | | | | | | | | | | | | | šii | | |
| | Sodium | carbonate. | | | | | | | | | | | | | | 311 | 11 | |
| Μ. | | | | | | | | | | | | | | | | | | |

Formic Acid as a Tonic After Diphtheria.—In doses of from five to twenty minims of a twenty-five per cent. solution, formic acid is recommended for its tonic and stimulating effects in convalescence from diphtheria, by C. B. Kerr and D. H. Croom. It is given in the doses stated every four hours.—Berliner klinische Wochenschrift, June 22, 1908.

NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal and The Medical News.

A Weekly Review of Medicine.

Edited by

FRANK P. FOSTER, M. D., and SMITH ELY JELLIFFE, M. D.

SUBSCRIPTION PRICE

Under Domestic Postage Rates \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Untered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, JULY 18, 1908.

"THE OPERATION WAS SUCCESSFUL, BUT THE PATIENT DIED."

This hackneyed statement has long been a favorite with those who delight in a "policy of pin pricks" directed against the medical profession, and few are the penny a liners who are above the temptation to use it, on account of its supposed humor, without any real intention of casting a slur on operative surgery. And yet it is quite conceivable that it was first employed by a surgeon and with perfect propriety. Many a surgical operation has been begun and abandoned unfinished. The difficulties may have been foreseen, and yet the operator, acting to give his patient the only chance, has hoped that they would prove less serious than he had supposed, but only to meet with disappointment. Again, difficulties not at first expected may have shown themselves in the course of the operation. Such occurrences result in an unsuccessful operation. If the obstacles to the completion of an operative procedure, whether expected or unforeseen, are overcome, the operation is correctly classed as successful, no matter what the final result to the patient may have been. No experienced surgeon needs to have instances of either of the causes of failure which we have mentioned brought to his attention; he will readily recall them from his own observation.

The situation is not without parallel in other than surgical undertakings. Last Sunday the New York Times published a picture the legend of which was as follows: "Transplanting an oak tree sixty feet in height. A locomotive crane moved this tree 200

feet recently at Ampere, N. J., and it was replanted with success." Now, what does "with success" mean in this legend? The employment of the word "recently" seems to imply that not enough time had elapsed since the undertaking was carried out to establish the fact that the great tree lived and flourished after its accomplishment. We all know that the transplantation of a large tree is a piece of work that calls for exceeding carefulness if the tree is to take to its new site and maintain its life. Some of its vicissitudes, some of the elements that preclude its continued life and growth, are perhaps beyond our ken, but we do know that, unless certain precautions are observed, ultimate failure is inevitable. If these known requisites are complied with, the transplantation itself (the analogue of a surgical operation) may properly be described as successful; if the unknown requisites alone have not been met, the tree languishes and finally dies, but in the light of our present knowledge, no fault can be found with him who declares that the process of transplantation was successful.

A REVISED NOMENCLATURE AND CLASSIFICATION OF DISEASES.

We would call particular attention to a circular recently issued by Dr. Cressy L. Wilbur, chief statistician of the Bureau of the Census, concerning the work of revising the nomenclature and classification of diseases and injuries, undertaken by a special committee of the American Medical Association acting in conjunction with the Bureau of the Census, the government medical services, and various medical organizations. We print Dr. Wilbur's circular in our department of Miscellany this week. The committee will be glad to receive suggestions from any source. They may be addressed either to Dr. Wilbur, Bureau of the Census, Washington, D. C., or to the chairman of the committee, Dr. Frank P. Foster, 554 West 114th street, New York. It is desirable that they should be received before October, as the work of arranging them for the committee's consideration will necessarily take a good deal of time, and after that the final revision will have to be made.

The nomenclature drawn up by a joint committee appointed by the Royal College of Physicians of London has been largely followed in this country for a number of years now, and it is thought that it should be departed from in the proposed new nomenclature as little as may be consistent with accuracy and logical arrangement. Physicians who are willing to offer suggestions to the committee are therefore asked to examine that nomenclature in connection with any changes that they may be

disposed to recommend. The fourth edition (third revision) should be used. It is a book of 496 pages, published in London in 1906, and may be obtained by sending the price (one shilling) to Wyman & Sons, Ltd., Fetter Lane, London, E. C., England.

THE CLINIC FOR TUBERCULOUS DISEASE A MEANS OF GENERAL DISPENSARY IMPROVEMENT.

In our issue for May 16th there was published a suggestive and stimulating article by Dr. James Alexander Miller, president of the association, on the results achieved and the plan of campaign for the future of the Association of Tuberculosis Clinics of the City of New York. The cardinal and effective features of the work of this association, which has demonstrated its usefulness as a centre in the warfare against tuberculous disease in this city, are the principles of cooperation and division of the city into districts for efficient and united effort. A remarkable feature has been the cordial support and recognition, both lay and professional, which has been accorded the plans of the association from its inception.

We believe that the principle of limitation of out patient activities to a specified district is a valuable step forward which will not be confined to the treatment of tuberculous disease alone. Its many obvious advantages in a city of the size and topography of New York are certain in time to insure its adoption for every phase of general outdoor relief. The saving for the indigent patient in expense and time away from his employment, the elimination of the hospital rounder and all wasteful duplication, the economy of effort for the visiting nurse and social service department, which are now essential parts of the modern, well equipped dispensary, and above all the closer personal relations with the patient which the district system makes possible are benefits not to be lightly considered. The well directed enthusiasm of workers in the campaign against tuberculous disease promises to result in a general awakening to the possibilities of increased efficiency in the care of all classes of ambulant patients.

There has been in this country a curious inconsistency, which is not to be found in the best institutions abroad, in the status of the patient in the out patient department and the same patient when transferred to a ward. In the former case almost any kind of routine treatment has been considered good enough, records have been poorly kept, laboratory examinations have been too rarely made, the physician has been hurried and insufficiently provided with the necessary appliances for insuring the best results, and there has been only too often a

want of scientific pride and spirit of thoroughness which should accompany medical effort wherever performed. All this has long been appreciated by the men actually engaged in the classes. The conditions, however, have appeared discouraging and almost hopeless as to remedy, on account largely of the apparent indifference of hospital managers and medical boards to the needs of their out patient departments. The dispensary has too long been the neglected stepchild of the hospital.

Perhaps the first step toward a real betterment of the situation was taken some two years ago, when, in an important address before the Presbyterian Hospital Alumni Association of New York, Dr. Richard C. Cabot clearly pointed out the existing evils and insisted upon the necessary rôle of the dispensary as an integral part of any adequate hospital system. He also in a convincing manner indicated the methods to pursue in improving the character of the medical service, and emphasized the value of district nursing and social service as developed in his own work in Boston. These fruitful ideas in New York have perhaps most promptly and energetically taken root in the field of tuberculous disease, the time being ripe on account of the widespread and growing interest in this direction, and the recognition of the fact that this great and necessary work lies entirely outside of the domain of the hospital proper.

THE UNDERGRADUATE MEDICAL ASSO-CIATION OF THE UNIVERSITY OF PENNSYLVANIA.

The May number of the University of Pennsylvania Medical Bulletin is devoted to the publication of the papers read at the first annual meeting of the Undergraduate Medical Association of the University of Pennsylvania, which was held on April 8th. There are connected with the university a number of undergraduate medical societies, which have been organized partly for social and partly for scientific purposes. Each of these societies is a member of the Undergraduate Medical Association, and each appointed a representative to read a paper at this, the first annual meeting. The association is organized and worked after the plan of the American Medical Association. A casual glance at the papers published indicates that the men who prepared the scientific material for this meeting, all of whom are members of the graduating class, have contributed a very creditable collection of interesting articles. We have always thought it a pity that the old requirement of a thesis for graduation was abandoned; here we see a method of reviving it, on a small scale, to be sure, but in a way that will be

of great benefit to the men taking part in the scientific work of the meetings. Dr. Talcott Williams was the orator of the day, and he spoke of the life of Dr. S. Weir Mitchell.

CARCINOMA.

"The cause of carcinoma—the subtlest of human diseases today—is essentially a biological problem the attempted solution of which has drawn out many wild guesses, not a few misapplications of biological principles, and some good working hypotheses," writes G. N. Calkins in the May number of the Journal of Experimental Medicine in opening a discussion on the so called "rhythms of growth energy in mouse cancer."

In the numerous studies of the Jensen mouse cancer it has been clearly established that, like many free living cells-Calkins has shown it for Paramecium aurelia and Woodruff for Oxytricha fallax -there are periods of growth activity which alternate with periods of depression of vitality occurring at more or less rhythmical intervals. Bashford, Murray, and Boyen have accumulated considerable evidence bearing on this point for the mouse tumors, and the plottings of their results show curves of alternate growth waves arguing for the correlates of rhythms of growth energy in the cancer cells. While Calkins holds that the results obtained by these investigators may be interpreted along different lines, yet the tendency of their argument is in accord with some of his own experiments, that there is a regular variation in the energy growth of the cancer, the source of the alternate rhythm of which must be sought in the cells.

These cancer cells get their nourishment as do other epithelial cells; they are bathed by the same fluids, and are subject to the same general conditions of metabolism, but other epithelial cells do not multiply as the cancer cells of mice do. The cancer problem has, then, to do with the specific attribute which distinguishes the cancer cells from these other epithelial cells, and once more one is face to face with the underlying why and wherefore, as to the source of the stimulus which causes the infectivity combined with the increase of the division energy.

Calkins argues that the cells themselves must carry with them the sources of their stimuli, and that these stimuli must be the same, both in the primary tumor and in the secondary tumors which develop therefrom, and when in addition it is found that rhythmical variations in growth energy are found comparable to what one finds in unicellular organization, the conductor mevitable, to the author, the conductor it is finally to development is within, or associated with the cancer cell itself.

The Cohnheim test then falls before the biological requirements. The hypothesis of Ribbert does not permit of the perpetuation of the energy stimulus; the chemical theories of Marchand do not allow of the continuation of the initial stimulus, and gradual loss of energy is the consequence; and so Calkins argues that the "cause of the division energy lies in the stimulating poison of some self contained and ordinarily invisible microorganism whose rhythmical variations in vitality may possibly account for the rhythmic variations in infectivity."

That we have found no parasite of course proves nothing. The rhythms in growth energy of the Jensen mouse tumor are not precisely like those known for the protozoa thus far studied, but the author throws out the suggestion that in the newly found spirochætes there is a possibility that the group of organisms may be found that is at the foundation of the cancer problem.

"THE DIRTY CUFF."

Under this heading the Lancet, in its issue for July 4th, deprecates the wearing of shirts that are not altogether white, intimating that colored shirts are worn chiefly by persons who seek to conceal the soiled state of the shirt. "There can be no doubt at all," says our contemporary, "that, when the cuff picks up, as it is so prone to do, dirt from the counter, desk, or table, it picks up also a multitude of microorganisms." But is the colored shirt so generally preferred for the reason that it can be worn longer than the white shirt without looking soiled? We doubt if it is as a rule. Certainly the colored shirt is worn on all but formal occasions by men who are most exacting in the matter of cleanliness, men who could not endure to go dirty and who could not overlook the soiling of their linen even if it was made of "dark goods."

The widespread preference for the colored shirt is due, we believe, to the fact that it can be worn with the bosom unstarched and still not offend sticklers for appearances. Those sticklers are so outspoken, however, that it must at first have taken some courage to revolt against the heat and stiffness of the starched shirt bosom. We wish that men would carry their courage a little further and refuse to wear the starched collar, that most uncomfortable of articles for weather that is at all warm. Regard for comfort, within the bounds of decency, is in no wise incompatible with one's natural liking for cleanliness or with one's just deference to the reasonable demands of others. But fashion is tyrannical, and we must wait for an era of higher civilization before we can ignore her behests, however senseless they may be.

Some of the garments usually worn by women seem to be much more comfortable than the analogous articles to which men are accustomed, but women go on tolerating flowing sleeves (when they are in fashion), long skirts, and oppressive corsets. Who shall say that women are dirty because they so commonly wear colored gowns? Their trailing skirts do, indeed, become dirty and reeking with microorganisms, but not the colored ones any more than those which are white. The lower border of a skirt collects its dirt on the inside, where it is invisible, so that an uncleanly woman would gain nothing by wearing colored skirts instead of white ones. Moreover, we believe that the cuffs of the colored shirt waist are quite as likely to be spotlessly clean as those of the same garment made of white goods. Things are not always what they seem, and it is hardly fair, we think, to take it for granted that a colored shirt marks an uncleanly man.

Rems Items.

Personal.—Dr. Charles Phillips Emerson was inaugurated as superintendent of the Clifton Springs Sanatorium, Clifton Springs, N. Y., on July 9th.

A Statue of Queen Alexandra at the London Hospital was unveiled on July 10th, the occasion being suitably celebrated.

The Geneva, N. Y., Medical Society held its regular monthly meeting on the evening of July 16th. The principal feature of the programme was a paper by Dr. Skinner.

A Department of Hygiene and Physical Culture has been established at the Massachusetts Agricultural College, with Dr. Percy L. Reynolds as director.

Changes of Address.—Dr. Brooke M. Anspach, to 119 South Twentieth Street, Philadeiphia; Dr. Ralph N. Prentiss, from Holyoke, Mass., to 1212 Kings Highway, Brooklyn N. Y.

The Eleventh French Medical Congress will convene at Geneva, Switzerland, on September 3d. The French railways have announced 2 reduction of fifty per cent. in the railway fares of physicians attending the congress.

The Douglas Hospital of Philadelphia laid the corner stone of its new building on Sunday, June 28th. The Frederick Douglas Memorial Hospital is officered and managed exclusively by negroes. There is a training school for nurses in connection with the hospital.

The Free Distribution of Diphtheria Antitoxine by the State Department of Health of Pennsylvania has resulted in the saving of nearly 8,000 lives, according to the statement of Health Commissioner Dixon in a paper read before the Pennsylvania Pharmaceutical Association.

The Care of the Baby is the title of a thirty-two page illustrated pamphlet just issued by the Illinois State Board of Health for gratuitous distribution. The pamphlet gives sound advice on the question of the feeding and care of infants, and the information is put in simple, direct language. This is the fourth revised edition of the pamphlet.

Appointments at the University College of Medicine, Richmond, Va.—At a recent meeting of the board of trustees of this college, six new professors were added to the faculty, as follows: Dr. A. G. Brown, Jr., professor of the theory and practice of medicine; Dr. J. Garrett Nelson, professor of practice of medicine and physical diagnosis; Dr. McGuire Newton, professor of pædiatrics; Dr. William J. Cowardin, professor of orthodontia; Dr. William Pilcher, professor of prosthetic dentistry; and Dr. M. B. Rudd, professor of metallurgy.

The Mortality of New Orleans, La.—During the month of June, 1908, there were reported to the Board of Health of the City of New Orleans 566 deaths from all causes, 344 white and 222 colored. The annual death rate in 1,000 of population was 16.00 for the white population, 28.64 for the colored, and 19.35 for the total white and colored.

An English Physician a Centenarian.—Sir Henry Pitman, M. D., of London, celebrated his one hundredth birthday on July 1st. He received congratulatory messages from King Edward, the council of the British Medical Association, and the Royal College of Physicians and Surgeons, the latter body presenting to him a handsome piece of plate.

Research Work in Nutrition in the Tropics.—Dr. Hans Aron, of Berlin, Germany, has been appointed professor of physiology in the Philippine Medical School, Manila. Dr. Aron will devote special attention to the question of tropical foods, and the Philippine administration has placed \$2.000 at his disposal for the purchase of laboratory apparatus.

Cancer Research.—An international association to promote research work in cancer has been established in Bertilin. The principal objects of the association are the establishing of an international centre of information on matters relating to cancer research, and the collection and publication of cancer statistics. An effort will be made to organize international cancer conferences.

Charitable Bequests.—By the will of William Farr, the Pennsylvania Hospital and the Wills Eye Hospital, Philadelphia, will each receive the surplus of the estate for the endowment of free beds to be known as the Mary G. Farr Free Beds.

By the will of Elizabeth Renz, the German Hospital, Philadelphia, and the Philadelphia German Protestant Home for the Aged, of Philadelphia, become contingent beneficiaries.

Diet Kitchens in New York.—The New York Diet Kitchen Association announces that another station, the eighth, is about to be opened near Columbus Avenue and One Hundredth Street. Stations are now maintained at 437 West Forty-first Street, 160 Mott Street, 146 West Seventh Street, 265 East Sixty-sixth Street, 1636 Lexington Avenue, 26 Barrow Street, and 205 West Sixty-second Street. The kitchens supply certified milk for destitute children without charge.

The Health of Pittsburgh.—During the week ending July 4, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 2 cases, 0 deaths; typhoid fever. 20 cases, 4 deaths; scarlet fever, 13 cases, 1 death; diphtheria, 6 cases, 0 deaths; measles, 95 cases, 5 deaths; whooping cough, 11 cases, 1 death; pulmonary tuberculosis, 26 cases, 6 deaths. The total deaths for the week numbered 148, in an estimated population of 565,000. corresponding to an annual death rate of 13.61 in 1,000 of population.

The Seventy-sixth Annual Meeting of the British Medical Association will be held in Sheffield, England, July 24th to 31st. The address of the president, Dr. Henry Davy, will be delivered in the Firth Hall of the University on July 28th. The address in medicine will be delivered by Dr. James Kingston Fowler, and the address in surgery by Mr. Rutherford Pye-Smith. Professor Edmund Owen will deliver a popular lecture on Dust and Disease. There will be seventeen scientific sections, which will meet on Wednesday, Thursday, and Friday, July 29th, 30th, and 31st. An extensive programme of papers to be read has already been published.

Medical Day at Willow Grove.—The social reunion of physicians from southeastern Pennsylvania, Delaware, and western New Jersey, which takes place on the afternoon and evening of Wednesday, July 22d, at Philadelphia's suburban resort, Willow Grove, promises to be a great success. An effort is being made to include in the gathering all medical societies that hold social meetings during the summer season, and each society will be afforded an opportunity to hold its individual meeting, if desired. Otherwise the formal programme will be omitted. Officers of participating bodies will act as a committee of the whole to attend to the comfort of the visitors. The guests of honor will be Dr. Joseph D. Bryant, of New York, and Dr. William L. Estes, of South Bethlehem, Pa.

The Drinking Water on Railway Trains.—As a result of recent investigations, the Department of Health of the State of New York reports that the water supplied passengers on railway trains in the state corresponds in quality to that of the cities and towns through which the roads pass. The supply is usually drawn from the city supply at relay stations, though on the dining cars special spring water is furnished on most lines. In a few instances only was the source of supply open to objection, and it is understood that in these a change will be made.

Officers of the Reserve Medical Corps.—Commissions for more than 150 surgeons as officers in the Reserve Medical Corps of the Army have been made out and forwarded to President Roosevelt for signature, we learn from the Army and Navy Journal. Physicians in good standing who would like to serve in case of war should apply for appointment in the Reserve Corps. No salary is received save while in active service, and no one can be ordered on active service against his wishes. An appointment does not conflict with militia service, and a special effort is being put forth to secure the applications of all the medical officers of the militia now in service. *

The Telephone as a Factor in the Transmission of Disease was recently made the subject of an interrogation in the English Parliament. In England the telephone service is a government affair, being conducted by the postal authorities. The question was brought up by an article by Dr. Allan, published recently in the Lawcet, in which the statement was made that disease germs were found in one out of six public telephones. The Postmaster General declares that none of the numerous devices for the prevention of infection of the transmitters have proved practicable, and that the only safeguard against infection is frequent washing.

Brooklyn Charities Cooperate in Work for Babies.—Under the general supervision of the Brooklyn Children's Aid Society many of the charity associations of Brooklyn have begun work under a cooperative plan in behalf of the lives and general health of babies. The plan involves the division of the crowded portion of Brooklyn into three sections. Greenpoint, East New York or Brownsville, and the river front south of the Brooklyn Bridge, and these larger sections, in turn, into smaller districts carefully mapped. All newborn infants and all who are ill will be visited and looked after, as occasion may require, the children and their mothers being sent to the mountains or the seashore where it is deemed necessary.

Infectious Diseases in New York:

We are indeleted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending July

| m 1 | Cases. Dea | ths. C | July 1: ases. De | aths. |
|------------------------|------------|--------|---------------------|-------|
| Tuber value pulmonali | 374 | 150 | 444 | 107 |

| Table | T 141 | 221 | | -00 |

The Tri-State Medical Society of Illinois, Iowa, and Missouri.—The sixteenth annual meeting of this society will be held in Ottumwa, Ia., on Tuesday and Wednesday, September 8th and 9th. According to the programme which has been prepared this meeting promises to be one of the greatest in the history of the organization. Over sixty papers covering a wide range of subjects of interest to the general practitioner will be read by prominent members of the medical profession. The president's address on Recent Progress in Medicine and Surgery will be delivered by Dr. Godfrey Oldfield Cuppaidge, of Moberly, Mo., on Tuesday evening. On Wednesday morning officers for the year 1900 will be elected. The present officers of the society are: President, Dr. G. O. Cuppaidge, of Moberly, Mo.; first vice president, Dr. C. C. Cochran, of Jacksonville, Ill.: Dr. Felix W. Garcia, of St. Louis, Mo.; secretary, Dr. Joseph E. Chambers, of St. Louis, Mo.; treasurer, Dr. Emory Lauphear, of St. Louis, Mo.; treasurer, Dr. Emory Lauphear, of St. Louis, Mo.

Assistant Surgeons Wanted for the Public Health and Marine Hospital Service.-A board of medical officers will be convened to meet at the Bureau of Public Health and Marine Hospital Service, 3 B Street S. E., Washington, D. C., on Monday, September 14, 1908, at 10 a. m., for the purpose of examining candidates for admission to the grade of assistant surgeon in the United States Public Health and Marine Hospital Service. Candidates must be between twenty-two and thirty years of age, graduates of a reputable medical college, and must furnish testimonials as to their professional and moral character. The examination will be physical, oral, written, and clinical. In addition to the physical examination the can-didate will be required to certify that he believes himself free from any ailment which would disqualify him for service in any climate. The written examination begins with a short autobiography of the candidate, and consists of questions bearing on the various branches of medicine, surgery, and hygiene. The oral examination includes subjects of preliminary education, history, literature, and the natural sciences. The clinical examination is conducted at a hospital, and, when practicable, candidates are required to perform surgical operations on a cadaver. After four years' service assistant surgeons are entitled to examina-tion for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority. Assistant surgeons receive \$1,600 a year, passed assistant surgeons receive \$2,000, and surgeons Furnished quarters are provided for officers and their families, and where this is not practicable, commutation at the rate of \$30, \$40, and \$50 a month, according to grade, is provided. The tenure of office is permanent. For further information address the Surgeon General of the Public Health and Marine Hospital Service. Washington, D. C

The Health of Philadelphia.—During the week ending June 27, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 34 cases, 6 deaths; scarlet fever, 30 cases, 1 death; chickenpox, 14 cases, 0 deaths; dipitheria, 51 cases, 2 deaths; cerebrospinal meningitis, 1 case, 0 deaths; measles, 148 cases, 6 deaths; whooping cough, 48 cases, 6 deaths; plumonary tuberculosis, 100 cases, 53 deaths; pneumonia, 20 cases, 20 deaths; erysipelas, 3 cases, 0 deaths; puerperal fever, 3 cases, 1 death; mumps, 5 cases, 0 deaths; cancer, 20 cases, 33 deaths; retanus, 2 cases, 0 deaths; cancer, 20 cases, 34 deaths; telanus, 2 cases, 0 deaths; cancer, 20 cases, 34 deaths; telanus, 2 cases, 0 deaths, The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 8; diarrhea and enteritis, under two years of age, 55; dysentery, 2 cases. The total deaths for the week numbered 500, in an estimated population of 1,532-738, corresponding to an annual death rate of 1603 in 1,000 of population. The total infant mortality was 165; under one year of age, 143: between one and two years of age, 22. There were 44 still hirths; 29 males, and 15 females. The total precipitation was 0.03 inch. The maximum temperature was over 80° every day, except the 26th, when it was 78°. There were 5 deaths from heat and sunstroke; 2 adults and 3 minors.

During the week ending July 4, 1008, the following cases were reported: Malaria fever, 2 cases, 0 deaths; typhoid fever, 34 cases, 4 deaths; scarlet fever, 24 cases, 3 deaths; chickenpox, 6 cases, 0 deaths; diphtheria, 61 cases, 13 deaths; measles, 141 cases, 6 deaths; thooping cough, 43 cases, 12 deaths; pulmonary tuberculosis, 120 cases, 60 deaths; pneumonia, 21 cases, 28 deaths; erysipelas, 5 cases, 1 death; pneumonia, 21 cases, 28 deaths; trachoma, 2 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 13; diarrhea-and enteritis, under two years of age, 96; cholera morbus, 1; tetanus, 1. The total deaths for the week numbered 521, in an estimated population of 1,532,738, corresponding to an annual death rate of 17,61 in 1,000 of population. The total infant mortality was 100; under one year of age, 158; between one and two years of age, 32. There were 45 still births; 27 males, and 18 females. The total precipitation was 0.09 inch. The maximum temperature was above 80° every day. There were 17 deaths from heat and sunstitude, 7 adults, and 1 minutes.

The Medical Society of the County of Ontario, N. Y., The Medical Society of the County of Untario, N. Y., held its regular quarterly meeting on Tuesday, July 14th. The programme included the following papers: Pulmonary Complications of Typhoid Fever, by Dr. C. Lytle, of Geneva; Anæsthetics, by Dr. G. W. McClellan, of Canandaigua; When Should Local Anæthesia be Substituted for General, by Dr. M. B. Tinker, of Ithaca; The Relation of a Sound Heart to Surgical Operations, by Dr. John Parmenter, of Buffalo.

The Association of Scientific Societies of Japan held.

The Association of Scientific Societies of Japan held a reception in Tokio at the Ongaku-Kakko, at 2:00 p. m. on Tuesday, June 16th, in honor of Dr. Robert Koch, who recently landed in Japan on his trip around the world. who recently landed in Japan on his trip around the world. Baron Ishiguro delivered the opening address, and this was followed by the address of welcome, which was delivered by Professor Miura, president of the Medical Society of Tokio. Dr. Koch replied, and closing remarks were made by Professor Aoyama. At 7:00 p. m. a theatrical entertainment was held at the Kabukiza Theatre, the performance being opened by a speech by Baron Telegraph.

Takagi.

The Mortality of Chicago.—During the week ending July 4, 1908, there were reported to the Department of Health of the City of Chicago 440 deaths from all causes, as compared with 508 for the previous week and 456 for the corresponding period in 1907. The annual death rate in 1,000 of population was 10.59, which is the lowest death rate ever recorded in Chicago during the month of July, and is the lowest on record for any week since June 18, 1904. The principal causes of death were: Apoplexy, 10; Bright's disease, 32; bronchitis, 6; consumption 50; cancer, 26; convulsions, 6; diphtheria, 10; heart diseases, 47; influenza, 1; intestinal diseases, acute, 37; measles, 4; nervous diseases, 11; pneumonia, 33; 37; measles, 4; nervous diseases, 11; pneumonia, 33; scarlet fever, 2; suicide, 9; typhoid fever, 7; violence (other than suicide), 22; whooping cough, 4; all other causes, 123.

The Health of the Canal Zone.—During the month of May, 1908, the total mortality in the Canal Zone was 205, May, 1908, the total mortanty in the Canal Zone was 20% in a population of 117,827, corresponding to an annual death rate of 20.87 in 1,000 of population. There were 3 deaths from typhoid fever, 2 from malarial fever, 3 from astivo-autumnal malaria, 18 from clinical malaria, 2 from hæmoglobinuric fever, 1 from measles, 4 from amæbic dysentery, 6 from clinical dysentery, 2 from beriberi, 4 from purulent infection and septicæmia, 24 from tuberculosis of the lungs, 6 from other forms of tuberculosis, including general tuberculosis, 4 from carricular theuristics. culosis, 4 from carcinoma, I from acute articular rheumatism, I from bronchopneumonia, 25 from pneumonia, 21 from diarrhœa and enteritis, under two years of age, and 2 from diarrheea and enteritis, over two years of age The improvement in the sanitary conditions continues. The remarks made about the death rate of the different classes of the population in former published comments upon the health of the Canal Zone hold good for the report for May.

Philadelphia Bureau of Health Statistics .- During the Philadelphia Bureau of Health Statistics.—During the month of May, 1908, in the Division of Medical Inspection 2,390 inspections were made, exclusive of schools; 1,297 fumigations were ordered; 38 cases were referred for special diagnosis; 5,589 visits were made to schools; 693 children were excluded from school; 175 cultures were taken; 129 injections of antitoxine were given, and 392 persons were vaccinated. In the Division of Vital Statistics, 1876 deaths, 3,450 births, and 100 persons 392 persons were vaccinated. In the Division of Vitages were reported. In the Division of Milk Inspection 10.268 were reported. In the Division of Milk Inspection 10,208 inspections were made of .252.971 quarts of milk, of which 660 quarts were condemned. Nine specimens were examined chemically and 1,271 were examined microscopically. In the Division of Meat and Cattle Inspection 3.457 inspections were made; 482 pieces of dressed meat were condemned; 111 places were found unsanitary; 1,326 post mortem examinations were made, with 352 condemnations. In the Division of Disinfection 208 furnigations were made for scarlet favor; 208 for dishthetical tions were made for scarlet fever; 298 for diphtheria; 84 for typhoid fever; 269 for tuberculosis; 314 for miscellaneous diseases; and 32 schools were disinfected. In the Bacteriological Laboratory 1,052 cultures were examthe bacteriological Laboratory 1,052 cultures were examined for the presence of bacillus diphtheriæ; 268 speciments of blood were examined for the serum diagnosis of typhoid fever; 1,271 specimens of milk were examined; 130 specimens of sputum were examined; 8 disinfection tests were made; and 3,262,200 units of antitoxine were distributed. In the Chemical Laboratory 137 examinations were made.

Obscure Fever in Infancy and Early Childhood, By JOHN LOVETT MORSE.

3. Obscure Fever in Infancy and Early Childhood.-Morse speaks of fever accompanying endocarditis, typhoid fever, malaria, eczema, dentition, in the new born, toxic absorption from tonsils, and adenoids, otitis media, cervical adenitis, pyelitis, anæmia, rickets, syphilis, tuberculosis, intestinal toxæmia and autointoxication. Most important is chronic diffuse tuberculosis and tuberculosis of the internal lymph nodes, causing a continued elevation of temperature without physical signs. Tuberculosis of other organs in early life usually runs such an acute course and is accompanied by such definite physical signs that it is difficult to overlook or mistake it. The diagnosis of chronic diffuse tuberculosis and tuberculosis of the internal lymph nodes during life is always difficult and often impossible without the aid of the tuberculin test in some form. In cases in which the tuberculin test is inadvisable the presence of a fluctuating opsonic index may be of great value in diagnosis. A history of definite exposure to tuberculosis is also of great assistance in diagnosis. The absence of such a history does not, of course, in any way rule out tuberculosis. Judging from the frequency with which tuberculosis is found at autopsy in childhood, and from the number of healed tuberculous foci found in later life, it would seem probable that a large proportion of the obscure fevers of infancy and early childhood are due to tuberculosis. It is the author's belief, however, that hidden tuberculosis is comparatively seldom the cause of continued elevation of temperature in early childhood, and that in the majority of cases in which the fever is supposed to be tuberculous in origin, it really is due to disturbances of digestion or metabolism. The explanation of this comparative infrequency of tuberculosis as a cause of obscure fever in infancy and early childhood is presumably that at this period of life tuberculosis tends to dissemination and a rapidly fatal course. Chronic latent cases are consequently relatively rare. Acute elevations of temperature, due to intestinal toxæmia, in infancy and early childhood seldom cause trouble in diagnosis, as they are almost always accompanied by marked symptoms, such as vomiting, diarrhœa, or obstinate constipation. In some instances, however, these symptoms may be so slight as to apparently not account for the fever. Long continued elevations of temperature without very evident cause in infancy and early childhood are probably most often due to a mild grade of intestinal toxæmia. Intestinal toxæmia is especially likely to occur in children who are overfed or improperly fed, and it is especially likely to develop in warm weather when the digestive powers are enfeebled by the heat and when bacterial infection of the food is more common. Lack of fresh air, sunlight, and exercise are important predisposing factors. There is considerable difference of opinion, however, as to what element or elements in the food

are most likely to favor the development of this condition. Some believe it is the proteids, others the carbohydrates, and still others the fats. tain others believe that milk is usually at the bottom of the trouble, while others attribute it to the fat in the milk. The author's experience leads him to believe that in the majority of the chronic cases there is decomposition of the proteids, and that the symptoms are comparatively seldom due to an excess of carbohydrates. Such cases usually yield fairly promptly to a milk and starch diet combined with proper hygiene and mild laxatives. The object of the milk and starch diet is to change the intestinal culture medium and to thus modify the intestinal flora. Disinfection of the intestine is impossible; sterilization of the food is of little or no value. The carbohydrate diet, however, furnishes a medium on which the putrefactive bacteria do not thrive, favors the growth of antagonistic bacteria, and thus diminishes the proteid putrefaction and intestinal autointoxication. Buttermilk is often useful in these cases for the same reason.

- Elements of Psychiatric Prognosis, By F. X. Dercum. Epidemic Infantile Paralysis, By M. ALLEN STARR. The Optical Nerve Changes in Multiple Sclerosis. With Remarks on the Causation of Nontoxic Retrobulbar Neuritis in General, By WARD A. HOLDEN.
- 1. The Coordination of Single Musuclar Movements in the Central Nervous System.-Beevor states that we may have, in any single movement, such as the closure of the hand, the following classes of muscles taking part: The prime or principal movers, the flexors of the fingers and thumb; the synergic muscles, the extensors of the wrist; and the fixation muscles, the triceps and biceps. The principal movers frequently consist of two or more muscles, and these muscles, as in the case of the flexors of the elbow and of the extensors of the hip, come into action in a definite order according to the amount of work required to be performed, and, further, it seems that the will has no power to alter this order or to make a muscle act out of its turn (except, perhaps, by trained exercises). Again, in those muscles which have two or more movements by passing over two or more joints, the synergic muscles come into action at the same time as the principal movers, and here again the will has no power to prevent these muscles acting or to leave them out of the list. Lastly we have the fixation muscles, which fix the joint or joints intervening between the joint under examination and the trunk, and which do not come into action until a certain pressure and displacement has been brought to bear on the joint. It seems probable that the mechanism by which the muscles taking part in a single movement are linked together, is situated in the cells of the posterior cornua of the spinal cord, which cells are acted on by impulses from the excitable cerebral cortex. As example he cites the action of supina-

- tion of the foramen. If only a weak action is required, as in simply moving the limb, the impulse coming to the posterior cornual cells is weak, and these cells send a mesage to the anterior cornual cells of the supinator brevis only. If stronger action is required, a stronger impulse is sent to the posterior cornual cells which stimulate the anterior cornual cells of the biceps, and at the same time those of the triceps which act synergically to prevent the elbow from being flexed by the biceps. If a stronger movement still is required, the fixation muscles, viz., the adductors of the shoulder, are brought into action by the posterior cornual cells to prevent the humerus being drawn away from the trunk by the very strong pressure to be overcome.
- 2. Insanities Caused by Acute and Chronic Intoxications with Opium and Cocaine.—Gordon has observed 171 such cases, and he remarks that if an attempt is made to find in acute or chronic morphinism and cocainism any of the well known forms of psychosis, a total failure follows. Some cases may simulate melancholia, mania, manic depressive insanity, and even paranoia, but in none of them can be found the typical pictures of these psychoses. Outside of the special tactile hallucinations of cocainism, we find in the acute form sometimes a delirious or a stuporous state. An element of confusion always accompanies them. Hallucinations of sight and hearing are frequently present. In the chronic form, the part which gives us the most concern, we do not find any of these psychoses in their typical forms, but we do find vague manifetsations, as delusions of a transient, fleeting, and fragmentary character. It is true that at certain periods of their evolution the latter assume the form of systematized ideas and conceptions, reinforced by hallucinatory images, and thus may present a picture of paranoia or other forms of insanity, but the ensemble of the condition does not permit us to consider them as such. A characteristic symptom is the gradually oncoming dementia, which develops very insidiously in the inveterate habitués, and increases with years until a complete psychic decrepitude is established. It is this threatening progressive quantitative diminution of mental power that presents the alarming problem for us when we are called on to counsel and render assistance to the community. When we compare intoxications from other sources with that of our present study we do not find any essential difference. Each agent may add a new special symptom, as, for example, the tactile hallucinations of cocainism, but the fundamental clinical picture in all remains invariably identical. In the acute forms there is a confusion of all sorts of mobile and contradictory conceptions, a dissociation of all elements of normal psychic life. Hebetude, stupor, and amnesia follow. These manifestations may be accompanied by hallucinatory images and sometimes superimposed by incidental delirious states. Not infrequently is observed a dreamy state, which is the continuation of dreams occurring during the night. The images seen by the patient in his dreams are confounded with the impressions of real life and thus increase the contradiction of conceptions. In the chronic form all varieties of intoxications invariably lead to the gradual enfeeblement of mentality, viz., dementia.

4. Clinical Observations on Antigonococcic Serum. - Uhle and Mackinney have treated twenty-three patients with antigonococcic serum. They observed that none of the patients suffering with gonorrheal prostatitis were cured. Of seven patients with epididymitis, improvement was observed in three, no improvement in four. These three patients were confined to bed, with elevation of the scrotum, and it is doubtful whether the improvement can be attributed to the serum alone. If conclusions can be drawn from this limited number of cases, say the authors, it appears that neither the number of injections nor the time elapsing between injections has any influence on the results of the treatment, as in no case was there what might be termed a prompt improvement, which is to be expected from an antitoxine treatment. Possibly better results would have followed the administration of larger doses. The best results were obtained in the patients suffering with arthritis. Three were promptly relieved, and all local evidences of inflammation had subsided in less than two weeks. In one of these Bier's treatment was used in conjunction. A patient with gonorrheal myositis showed but little improvement after two weeks' treatment with serum alone, but responded promptly when Bier's treatment was used in addition. Following the use of the serum injections a general urticarial eruption was observed in seven patients. Other than slight pain at the site of the injection and the urticarial eruption, accompanied by the most intense itching, no local or general toxic manifestations were observed.

7. Optical Nerve Changes in Multiple Sclerosis.-Holden states that disturbances of vision are found in about half of the cases of multiple sclerosis. Usually the dimness of vision is noticed early in the course of the disease, and it may come on long before any other symptoms have attracted attention. More than half of the patients with multiple sclerosis who complain of failing sight have central scotoma in the field of vision, and the ophthalmologic diagnosis of their condition is retrobulbar neuritis. Toxic cases of retrobulbar neuritis, due to poisoning with tobacco, alcohol, lead, and the toxines arising in pregnancy are readily recognized and diagnosticated as toxic. The causation of nontoxic retrobulbar neuritis, however, has often been obscure. We have learned recently that many of these cases are due to sphenoidal and particularly to ethmoidal disease, which involves the optic nerve in the optic foramen. He thinks that we shall soon come to the belief that a nontoxic retrobulbar neuritis, if not due to a sinusitis or directly to syphilis, diabetes, a neoplasm, or trauma, is, as a rule, a manifestation of multiple sclerosis, although no other symptoms of the disease may be present.

6. Some Cases, Other than Obstetrical, in which Hypodermic Injections of Ergot Have Been of Great Service.

By E. P. ROBINSON.

 The Conquest of the Venereal Diseases.— Ellis remarks that there are four methods by which in the more enlightened countries venereal disease is now beginning to be combated: (1) By proclaiming openly that the venereal diseases are diseases like any other disease, although more subtle and terrible than most, which may attack any one, from the unborn baby to its grandmother, and that they are not. more than other diseases, the shameful penalties of sin, from which relief is only to be sought, if at all, by stealth, but human calamities. (2) By adopting methods of securing official information concerning the extent, distribution, and variation of venereal disease, through the already recognized plan of notification and otherwise, and by providing facilities for treatment, especially for free treatment, as may be found necessary. (3) By training the individual sense of moral responsibility so that every member of the community may realize that to inflict a serious disease on another person, even only as a result of reckless negligence, is a more serious offense than if he or she had used the knife or the gun or poison as the method of attack, and that it is necessary to introduce special legal provision in every country to assist the recovery of damages for such injuries, and to inflict penalties by loss of liberty or otherwise. (4) By the spread of hygienic knowledge so that all adolescents, youths and girls alike, may be furnished at the outset of adult life with an equipment of information which will assist them to avoid the grosser risks of contamination, and enable them to recognize and avoid danger at the earliest stages.

Significance of Wash Water Examinations for Gastric Cells in the Diagnosis of Atrophic Gastritis.—Bassler describes his method in the following manner: The washing solution should in character and specific gravity approximate the blood. This is done by the addition of salines. The installation that was used contained 250 c.c. of water. to which were added 21 grains of sodium chloride, one grain each of sodium sulphate, sodium carbonate, and sodium phosphate, and 11/2 grains of potassium chloride. The empty stomach should be aspirated before the ingestion of the compound saline This is drunk, or run down through solution. the tube, the patient is made to exercise vigorously, or the fluid is agitated in the stomach by sharp taps with the hand upon the abdomen over the gastric region; it is aspirated after five minutes and permitted to stand for several hours, the upper part of the fluid is syphoned off, and the sediment, in small lots, centrifuged for examination by the microscope. The stains which have served him best are one half per cent. aqueous eosin, one per cent. methyl eosin and hæmotoxylin. Biondi's polychrome methylene and carbol fuchsin. He recommends for general use the eosin and hæmotoxylin. The acid cells from the stomach stain readily with most of the aniline dyes. They are seen between the leucocyte and squamous epithelium in

size, and their main features are their confluent stippling of the cell protoplasm with eosinophilic granules and their well defined nucleus. In shape they may be described as irregular, although most of them are oval. With the eosin and hæmotoxylin stain, which serves well in distinguishing the acid from the peptic cells (the first taking the eosin, the latter the hæmotoxylin), the nuclear membrane is usually well defined. The nucleus itself is usually lighter and a trifle larger than those in the peptic cells and stains in a blotchy way. These cells when desquamating in any numbers are easy to find, and upon their presence the main dependence must be placed in the diagnosis of atrophic gastritis. The peptic cells offer much greater difficulties in the way of their finding and discrimination than do any of the other organic elements found in the stomach. They stain poorly, the body just barely, the nucleus much better. With care and patience in the search they can often be seen, but never as plainly as the acid ones. Their cell protoplasm is indistinct and with the hæmotoxylin stain is found faintly bluish in color. At best they take eosin, or, in fact, any of the aniline stains, very poorly. Their nucleus stains deeply and generally uniformly throughout. Neither the nuclear membrane nor nuclear granules can be distinctly discerned. This also distinguishes them from the acid cells. The nucleus itself is seldom found oval, as is often the case in the parietal cells. They are much smaller in size than the latter, being in size between them and the leucocyte, for the mononuclear variety of which they may be mistaken. Because their protoplasm digests away so readily (when the cells are free) and because of their poor staining properties and the question of their presence even if seen, the search for them need not be continued when numbers of the more plainly recognized acid cells are discovered. Sometimes they take the carbol fuchsin stain better than they do the hæmotoxylin. The columnar cells from the stomach are not difficult to make out. It must be remembered that in the posterior nares and the upper half of the pharynx the epithelium is of the cylindrical variety, and these may be shed and swallowed. The cilia of these cells would serve to distinguish them from the gastric epithelium. They stain better than the peptic cells, although not so well as the acid. Their shape is characteristic, their protoplasm is not granular, and they have a long, flat looking nucleus which is almost in the centre between the ends of the cell, while in the acid and peptic cells the nucleus is generally nearer to the edge of the protoplasm. They are easily detached by the stomach tube and thus are not so significant in this connection, unless exfoliating in large numbers, as the peptic juice secreting cells would be. They are often found in groups, and hæmotoxylin stains them well. In cases of atrophic gastritis, particularly, there may be seen a ring of cells more or less complete, which consists of groups from the depths of the tubules. Sometimes a mass of rounded or cuboidal shaped cells may be exfoliated from the lower regions of the infundibula, and these would strongly resemble the first ones. The goblet cells are rarely found and are not difficult to distinguish from the true columnar.

2. Cystic Tumors of the Suprarenal Body.-Doran reports a case of unilocular blood cyst of the left suprarenal body, occurring in a woman aged sixty-two years. It was removed by operation, and the patient recovered. He also gives abstracts of thirteen other cases collected from the literature. The blood cyst of the suprarenal body is not a true new growth; it owes its origin to hæmorrhages into the medullary substance of the suprarenal capsule. Some pathological change within the organ is probably the sole cause in a majority of the cases. If the true character of the tumor be recognized during operation, the surgeon need not search for any extension of the disease in its vicinity. Adenoma, lymphoma, and other new growths seldom convert the suprarenal body into a cystic body. Pain is the most common symptom, usually assuming the character of dyspepsia or fits of colic, and leads to the discovery of a tumor. As regards the tumor itself, there is less fluctuation than in hydronephrosis, nor does the cyst descend so readily. Bronzing of the skin is very rare in benign cystic suprarenal tumors. The right treatment is removal by operation. It should be enucleated from the capsule of connective tissue in which it lies. Diagnosis is difficult; the best incision is a vertical one through the outer margin of the rectus. Incision and drainage alone is an unsatisfactory procedure. Pressure forceps should be applied to all large vessels in sight, no tissues being pinched in the dark.

3. Lateral Sinus Thrombosis.-Harrison reports two cases of lateral sinus thrombosis, one of which ended fatally. When the following group of symptoms are present together, septic thrombosis is certainly present: I. A history of purulent aural discharge for a year or more. 2. Sudden onset of the illness, with headache, vomiting, rigor, and pain in the affected ear. 3. An oscillating temperature. 4. Vomiting, repeated day by day. 5. A second, third, or more rigors. 6. Local tenderness and ædema over the mastoid or in the course of the jugular vein. 7. Stiffness of the muscles of the back or side of the head. 8. Optic neuritis. Jaundice is a frequent symptom, and the liver and spleen are

always enlarged.

4. Eczema.-Kesteren states that eczema is a pure neuropathia, and to regard it solely as a local affection is a grave misconception calculated to lead to serious error in treatment. But certain pathological states are frequently the indirect factors in the causation of eczematous attacks. The very nature of eczema-an exudative dermatitis due to capillary engorgement-indicates clearly vasomotor disturbance due to some morbific influence on the sympathetic centres of the nervous system. Eczema is a common concurrent of many functional and nervous derangements. It is so often associated with gout, that "gouty eczema" has been formulated as a specific type. Uterine disorders and pregnancy, together with mental cases-especially imbecilityare often complicated by eczema. Even where local irritation is the exciting cause of the attack, it still remains a neurosis. External toxic applications, friction, heat, cold, and the turgescence of varicosity are only the irritants of the peripheral filaments of the sensory nerves which set the eczema going. Eczema may thus be divided into two classes for purposes of treatment: (1) That from within, acting through the sympathetic chain of the functional system, may be denoted the ganglionic or idiopathic form, and (2) that arising from external or local irritation, the peripheral or traumatic. If a storm of gout has upset the sympathetic nerves and eczema has resulted, then the usual treatment for gout must be adopted, plus a direct nerve sedative. Acetanilid and potassium iodide act well, but colchicum should be avoided, as it dilates the capillaries. eczema of an asthenic type, from anæmia, the indication is iron with nerve tonics such as strychnine. If alcohol is the irritant, abstinence, with the bromides and atropine will bring alleviation. Dyspepsia, so frequently the exciting cause, calls for careful dieting, attention to the bowels, and such a nerve sedative as the bromides, to arrest the gastric nerve irritation. Eczema that accompanies uterine trouble disappears, as a rule, with its removal. Of the thousand and one local applications that have been recommended, only two or three are of any value. Nothing can compare, for the immediate and permanent relief which it confers, with carbolic acid, if properly utilized. It is a most powerful local anæsthetic, if used in sufficient strength, and the anæsthesia which it produces lasts a long time. Pure liquid carbolic acid applied to a red inflamed eczema gives sharp but short punishment and leaves the part practically dead. This dries rapidly, forming a scab under which the previously raw surface heals rapidly, the scab on falling off, leaving the surface clean and sound. Such heroic treatment must be applied only to limited areas at one sitting. For general use in all eczematous eruptions at every stage, the one to eleven solution should be used. Tincture of iodine also smarts somewhat, but gives great relief to the itching and burning. Suprarenal extract is a good application previous to the carbolic, owing to its power of reducing the turgescence and exudation. Greasy applications should only be applied in the dry and desquamative stage. Used in the moist stages they only aggravate the trouble by retaining the acrid irritating exudation. Soap, whether medicated or otherwise, should be religiously avoided.

5. Diving and Caisson Disease.-Mummery reviews the causes and symptoms of caisson disease as seen among divers. Mild symptoms of discomfort met with on beginning the descent, are usually speedily relieved by swallowing, which equalizes the pressure at the ends of the Eustachian tube. Dyspnœa, fainting, and syncope, if slight, may be due to de-

ficient air supply. If severe they are due to the diver having come up too quickly. Death is almost certainly due to embolism and blocking of cerebral or pulmonary vessels by the bubbles of nitrogen set free in the circulation by too rapid decompression. Paralysis, usually affecting the lower limbs, is not uncommon. Nausea and vomiting occur directly on the diver coming to the surface, and are usually due to a heavy meal just previous to descent.

- Nonmalignant Affections of the Stomach. -Eve gives his experiences of the surgical treatment of nonmalignant affections of the stomach. and sums up his conclusions regarding the choice of operations as follows: I. The operation of choice for ulcer is posterior gastrojejunostomy, without a loop. 2. Any form of enteroanastomosis should be avoided in ulcer, as it tends to diminish the flow of duodenal contents into the stomach, and it appears to increase the risk of peptic ulcer. 3. Finney's operation is attended by a higher mortality than gastrojejunostomy, is more difficult, and is contraindicated in ulcer, because the duodenal contents would not pass into the stomach. In stenosis, gastrojejunostomy gives better drainage, and the results are admirable. 4. Pyloroplasty is inefficient in stenosis. because the contraction frequently recurs. 5. Excision of a chronic ulcer is rarely feasible, and is attended by a high mortality. It should not be performed, because experience teaches that ulcers heal after gastrojejunostomy, although not placed in the pyloric or prepyloric regions. In five cases of ulcer situated in other parts of the stomach, the results of gastroenterostomy were absolutely good in four.
- 4. Malta Fever.—Eyre, in the third of his Milroy lectures on Malta fever or Septicæmia melitensis, takes up the channels of infection by which the micrococcus reaches its human host. The organism is not present in the expired air, nor has it ever been found in drinking or sea water, or in dust or earth. But laboratory experiments show that it retains its vitality and virulence for considerable periods when mixed with dry dust and soil, and

further that such contaminated soil can infect monkeys. Transmission of the disease by direct contagion has been constantly denied by all observers, but it is probable that it can occur during sexual congress. The author is decidedly inclined to the opinion that Malta fever is primarily a disease of the goat, which had its origin in the Persian hills, and which accompanied that goat on its world wide wanderings, and which has remained active for man as long as its host preserved its original habits in barren rocky countries and in the tropics, where pasturage is of the scantiest. When, however, the goat reaches temperate climes and abundant pasturage, and can no longer rival the cow as a milk giver, and selective inbreeding is in consequence neglected, the micrococcus no longer finds a suitable habitat in the caprine mammary glands, and rapidly disappears. The transmission of the disease from goat to goat may take place along any one or more of several channels: Cutaneous or subcutaneous inoculation is probably responsible for a large number of infections, the contagion being carried from goat to goat by means of the hands of the goatherd, soiled with infective milk. Connection by flies, which swarm in the goat pens, may also play a part.
5. Bacillus of Miscured Hams.—Klein has

found what he takes to be a specific microorganism in miscured hams, which he calls the Bacillus fadans. The hams in question were "dry cured," not having been pickled or injected. Miscured hams have a distinctly putrid smell, the muscles vary in color from a dirty gray to green, and may be swollen and jellvlike. The microscope shows disintegration of the muscle fibres, and numerous tyrosin crystals. The essential cause of the taint was one and the same species of cylindrical microbe. The decomposition is most pronounced at and around the knee. The bacillus is nonmotile, and spreads by forming linear chains and filaments. It is an obligatory anaerobe, requiring for its growth to be in the depth of tissues deprived of oxygen.

10. Premature Physiological Old Age.—Raymond states that the so called "family" diseases form a class of very peculiar maladies. No trauma, no infection, no intoxication, no diathesis gives rise to them. To become the victims of these diseases the subjects have only to be born of the same parents and reach the appointed age. They are not the expression of a struggle, but are the consequence of the original constitution of certain nerve tracts or cells. They can hardly be termed diseases, for they are really organic types abnormal from their very origin. The symptoms of the family nervous diseases depend entirely on the physiological functions of the tracts or cells that are doomed and are disappearing gradually. Any part of the neuromuscular system may be involved. The fammata in the race, and they should be grouped under the one heading-"Premature physiological senescence of certain organic systems. This physiological senescence is quite independent of any external factor; its date of onset varies with different subjects. It may be premature, and manifest itself at a period of life which is not that of normal senescence of the individual. The process is probably

not limited to the nervous system, but is probably very far reaching, and deserves to be put on a par with intoxication and infection, the two factors which at present govern medical pathology.

Ethyl Chloride as a General Anæsthetic in Daily Surgical Practice,
The Premenstrual Rheumatoid Fever of Young
Women.

By Fernand Lematrre.
Fever of Young
By R. Romme.

1. Interpretation of Urinary Analyses.—Labbe asserts that the determination of urea by the inexact methods called clinical are of no value or interest, while the accurate determination of the urea has no clinical interest simply and clearly defined. Urinary analyses, unless rationally conducted and logically interpreted, are not of practical value. The totality of the urinary principles are dependent on the nutrition and the mode of alimentation, and the variations of quantity and quality produced by alimentation are to be observed as more pronounced under pathological influences. These are to be studied best by means of the azote changes.

2. Ethyl Chloride as a General Anæsthetic.-Lemaitre considers ethyl chloride a useful general anæsthetic in every case in which an anæsthesia of not over two minutes' duration is required, and as a preliminary to other anæsthetics in cases where a more prolonged anæsthesia is required.

Material in Human Milk. By EHRICH MÜLLER. Excretion of Pepsin in the Urine, By G. G. WILENKO.

2. Pubotomy.—Krömer alleges that pubotomy and Cæsarean section are not concurrent operations, but that each is to be confined to cases in a certain well defined field. He considers pubotomy an operation from which recovery should be assured. The dangers to the patient are not from the sawing through of the bones, but from the too rapid passage of the child's head through the pelvis. In the majority of cases he finds that the bony cicatrix does not become firm, but remains movable, so that later pregnancies may follow a normal course and delivery

3. Bacteriology and Prognosis.—Liepmann's idea is that by making a bacteriological examination of a wound at the end of an operation it can be determined whether it is clean or infected, and that

this may influence the prognosis.

Pepsin and the Determination of Pepsin.-Wolff and von Tomaszewski say that juices with normal acidity have a tolerably constant fluctuating value of about 100 pepsin units. In hyperacid juices the fluctuations about the same average are greater. In subacid juices the average pepsin value is lower with relatively less fluctuations, while in juices which are not acid the pepsin value is very low, so long as the absence of acidity is not of nervous origin. Within each of these groups there is no parallelism between acidity and pepsin value. Ulcers seem to be associated with approximately normal pepsin value. In gastric catarrh the relative amount of pepsin and acidity are fairly parallel; carcinoma is ordinarily associated with a low pepsin value, though it may be quite normal. Neuroses appear to increase the pepsin value, which in these conditions reaches its highest mark.

6. Bisystole of the Left Ventricle and Arterial Symptoms in Insufficiency of the Aortic Valves. -Obrastzow says that in insufficiency of the aortic valves the left ventricle contracts in two periods, forming bisystole. Clinically this form of heart contraction is registered by certain peculiarities of the apex beat, the systolic reduplication of the first sound of the heart heard in the præcordial region, the cardiogram of the heart beat which shows two impulses, and the starting of two pulse waves in the great vessels which are demonstrable both by palpation and by the sphygmograph. The quick pulse in the peripheral arteries owes its origin to the disappearance of the first impulse of the divided pulse wave, which probably is lost in the second impulse or the second wave. This second blood wave is sent from the left ventricle with the greatest power of contraction, and therefore obtains a greater rapidity in the arterial system than the weaker first wave, so that it overtakes the latter, unites with it, and finally forms the quick pulse. It is probable that the systolic bruit from the aorta in insufficiency of the aortic valves frequently depends on the bisystolic contraction of the left ventricle by which the blood is caused to enter the great arteries in unstable equilibrium, and form a series of eddies with the blood already present, and that these cause the murmur. The same explanation would seem to suffice for the cause of the origin of the systolic murmurs in the aorta and pulmonary artery in severe anæmia.

By Zacharias.

Histological Changes in the Blood Forming Organs in Pernicious Anæmia.—Schatiloff reports four cases of pernicious anæmia with the final histological findings in each. The findings were briefly as follows: First case: The blood of the heart showed the typical changes of pernicious anæmia, numerous myelocytes, megaloblasts, and normoblasts. The hæmoglobine contents of the single cells was very high. In the spleen there was myeloid metaplasia and erythropoesis. The liver, lymphatic glands, and intestine were not specially changed. There was no lymphatic hyperplasia. The bone marrow was rich in megaloblasts. In the femur there were very numerous myeloblasts. Second case: Myeloid metaplasia in the spleen, absent in the liver, or at most intracapillary. No lymphatic hyperplasia, but diminution in the size of the follicles in the spleen. Third case: Erythropoesis and myeloid formations in the spleen (eosinophile and neutrophile myelocytes, bone medulla giant cells), to a less degree in the lymphatic glands, absent in the liver. No lymphatic hyperplasia. Megalocytes and megaloblasts in the blood of the heart and in the bone medulla, myeloblasts in less quantity. Fourth case: No erythropoesis in the spleen or liver, myeloid formations in the spleen but not in the liver, no lymphatic hyperplasia anywhere, but a diminution in size of the follicles of the spleen. Numerous megaloblasts in the bone medulla.

4. Congenital Syphilis of the Suprarenal Capsules.—Esser reports two cases in which infants died of syphilitic disease of the suprarenal capsules. and as among the reported cases of tuberculosis of the suprarenal capsules a considerable percentage presented no tuberculous lesions elsewhere, he suggests that congenital syphilis may be the cause of these isolated cases of tuberculosis of the suprarenal capsules.

5. Long Bacilli in the Fæces.—Sandberg as-

serts that he has published the method in which the presence of the long bacilli can be detected in the stools and distinguished from any other form of bacilli. The demonstration of the long bacilli in the stools may be of diagnostic value in the cases in which a washing out of the stomach is contraindicated, or for any other reason cannot be performed, and the presence of lactic acid suggests the existence of a malignant disease of the stomach.

7. Moderate or Radical Conservatism in the Treatment of the Narrow Pelvis.—Von Herff, after calling attention to the danger that the student will be so impressed by the brilliant results of radical interference in cases of narrow pelves as to neglect the study of other methods of management in these cases, asserts that a moderate conservatism in the treatment of the narrow pelvis with the aid of prophylactic interference is not only fully equal in its final results to, but is better than the radical conservatism based on the Cæsarean section and opening of the pelvis. Under all conditions such treatment is more humane and safer for the mother.

8. Cæsarean Section and Lumbar Anæsthesia.
—Polano reports three cases of Cæsarean section on patients under the influence of lumbar anæsthesia. All were successful from the viewpoints of both the operation and the anæsthesia.

g. Medicamental Prophylaxis of Measles.— Langer proposes the inhalation of a i in 30 solution of Merck's perhydrol for the purpose of preventing the spread of the disease, measles, to other children.

 10. Review of Clinical Pathology, By W. b'E. EMERY.
- 1. Progressive Muscular Atrophy.-Rankin states that this disease may affect the lateral coltimins as well as the anterior horns of the spinal cord, an atrophic change in the motor neurones being primarily responsible. The cause of the disease is unknown. It usually occurs in men older than thirty. Overwork, worry, exposure, trauma, and syphilis have been identified as influential in producing it. Myalgic pain is an occasional symptom. The wasting usually begins in the small muscles of one hand, and extends until most of the muscles of the arm and many of the trunk are atrophied. The muscles of respiration are ultimately involved. The reflexes may be impaired, but are not abolished until late in the disease. The disease continues for years, death usually resulting from some organic disorder, but it may come from extension to the bulbar mire in the medulla. The diagnosis is not usually

difficult, but it may be confounded with peripheral neuritis, syringomyelia, or lead poisoning, or muscular dystrophy. The best treatment consists in the hypodermatic use of strychnine. Arsenic and silver nitrate are also useful, also the ordinary tonic drugs. If syphilis is present, the proper antisyphilitic treatment is indicated. Massage, electricity, and radiant light baths are beneficial, and a dry, sunny climate should be chosen, if possible.

2. Suprapubic Prostatectomy.-Moynihan observes that mere enlargement of the prostate may not cause urinary difficulty; indeed, the gland may be smaller than normal, and cause all the usual bad symptoms. Prostatic disease seldom comes before the age of fifty, there is incapacity to empty the bladder, with stagnation of urine, and, sometimes. the formation of stones. Carcinoma develops in fifteen per cent. of the cases of prostatic hypertrophy. The surgical treatment is now so successful that an operation should be urged in the early stages of the disease. Of the two routes for operation, the suprapubic and the perinæal, the author prefers the former. The latter is preferred by many surgeons, and has given very brilliant results, but the former is simpler, and has given such excellent results to the author that he prefers it. He prefers to do the operation under spinal anæsthesia, injecting a small quantity of a ten per cent. solution of stovaine into the spinal canal. The mass of the prostate should be removed in one piece, including the prostatic urethra. The author has had eight deaths in a total

urethra. The author has had eight deaths in a total of one hundred operations.

3. Cholecystitis. — Monsarrat discusses the subject under the heads: (1) The different clinical types presented by the several stages and decrees

types presented by the several stages and degrees of cholecystitis, (2) their diagnosis, (3) the indications for operation. He remarks that the biliary concretion is not the prime factor in the cholecystitis. but it has a most important influence on the inflammatory attack, on its acuteness, and on the amount of damage done. Experimental work has shown that the sequence of events in cholecystitis is (1) an infection causing a catarrhal inflammation, (2) the formation of stones, (3) a persistent chronic cholecystitis which may be interrupted by acute attacks. Cholecystitis clinically is characterized by intermittent attacks, acute or subacute, with health usually imperfect between the attacks, but gross changes in the gallbladder are not incompatible with comparatively good health. In many of the cases ill health is continuous. Three types of acute inflammation are distinguishable, catarrhal, suppurative, and gangrenous. The indications for operation are such as point to urgent necessity in other types of acute intraabdominal inflammation. One attack of the disease is almost certain to be followed by others. The gallbladder should be removed when it is operated on for cholecystitis, if it is diseased to such an extent that it will not resume its function.

4. The Diagnosis and Treatment of Empyema of the Maxillary Antrum.—Connal divides this disease into the open and the closed variety. In the former pus discharges into the nostril, in the latter it is arrested by the swollen lining mucous membrane. In the former there is seldom pain, in the latter it is severe. One or both antra may be

diseased, and pus may discharge into one or both nostrils. The disease results in nasal polypi and hypertrophied mucous membrane, and secondarily in asthma, loss of smell, and discomfort from the offensive character of the discharge. In making the diagnosis, four tests are suggested, the postural, in which the head is bent forward and to the unsuspected side; transillumination of the antrum, with an electric lamp in the mouth; catheterization of the antrum, and exploratory puncture of the antrum. The treatment consists in draining the cavity and removing the cause. In the acute form of the disease, operation is seldom indicated; in the chronic form one may choose between the alveolar operation, through the alveoli of the teeth nearest the antrum, through the canine fossa, through an incision in the cheek, or through an opening in the nasal chambers.

6. Retrodeviations of the Uterus and their Treatment.-Bell thinks it is far too common to consider the actual deformity or displacement of the uterus, without considering the causal factors and the symptoms associated with it. The following types are mentioned: Congenital or developmental retroversion, especially in young girls, and usually without symptoms. Congenital or developmental retroflexion, with few symptoms until pregnancy occurs, and is followed by abortion. If persistent, after abortion, operative treatment will be necessary. Puerperal retroversion and retroflexion. This may be relieved by reduction, curettage, and 'the use of a proper pessary. If this treatment fails after six months' trial, an operation will be necessary. Pelvic inflammation associated with retroflexion and retroversion. Operation should be performed, but during the acute stage. Retroversion as an early stage of prolapse. This will require an abdominal operation, and usually one upon the perinæum. Retroversion caused by pelvic tumors or urinary retention, remedied by operation, with removal of the tumor. Traumatic retroversion. In this rare condition, replacement, with use of a pessary, if necessary, will usually suffice, otherwise an operation will be required.

Proceedings of Societies.

MEDICAL SOCIETY OF THE COUNTY OF

NEW YORK.

Meeting of April 27, 1908.

The President, Dr. J. RIDDLE GOFFE, in the Chair.

The Hygiene and Management of Pregnancy, Including the Examination of the Urine.—Dr. Austin Flint, Jr., read a paper with this title (see vol. lxxxvii, page 1131).

The Management of the Stages of Labor to Prevent Dystocia.—Dr. RICHARD C. NORRIS. Philadelphia, read this paper by invitation. He said that the prevention of inertia, hæmorrhage, and lacerations was in some respects antithetical. For the first, the labor must be hastened; to avoid the second, it must be neither too rapid nor too slow; and for the third, the termination of labor must be retarded. Individuals differed so in strength, endurance, and quality of tissue that the actual duration of the first and second stages of labor had and should have wide variations. An unduly prolonged

labor, from abdominal or uterine inertia, might often be expected in patients who lacked muscular tone, who were anæmic, and in whom there had been overdistention from twins, hydramnios, or tumors. Diastasis of the recti muscles, with a pendulous uterus, seriously interfered with proper direction of the forces of labor, and predisposed to exhaustion and inertia. A history of hæmorrhage after previous labors and the presence of a fibroid or of adhesions following any abdominal operation, especially hysterorrhaphy, frequently warned one of inertia and hæmorrhage. Of the various drugs to improve the blood's quality, and thus favor its coagulability and fibrin formation, he had more faith in the organic preparations of iron than in the calcium salts or in gelatin. The prophylaxis of hæmorrhage might, of course, begin during pregnancy, but it was of trifling value compared with the proper and skilful management of the three stages of labor. It had been his experience that, when the amniotic sac was unruptured, and there was delay beyond twelve hours in the first stage of labor, associated with nagging, inefficient pains, the condition was best treated with narcotics that allayed irritability and produced sleep. Ten or fifteen grains of chloral, repeated or reinforced if necessary by a sixth of a grain of morphine hypodermatically. would usually produce a sleep from which the patient would awake refreshed and with more efficient uterine contractions. He had but little faith in the efficacy of quinine for uterine inertia. He never used ergot during the first or second stages of labor. In multiparæ with two thirds dilatation, the membranes might be ruptured and so a slow and tedious first stage he shortened. In primiparæ, early rupture either increased the delay or predisposed to laceration of the cervix. An ædematous cervix nipped between the head and symphysis should not be forcibly stripped back over the head. A sterilized glycerin tampon held in contact with the lip of the cervix would often cause this obstruction to disappear. Following the sleep produced by the narcotic, further delay in dilatation of the cervix and lower uterine segment was best treated by artificial dilatation. Some one of the various anomalies of the cervix, spasm, rigidity, hypertrophy, or cicatricial contraction, might be the underlying factor in a prolonged first stage. If we recognized one of these, the case must not be left to nature. If bag dila tation or manual efforts after effacement of the cervix failed or were manifestly inappropriate, Dührrsen's incisions were indicated. Care should be taken to make these incisions free enough to avoid uncontrollable lacerations when the presenting part passed through the cervix. When the hypertrophy or contraction was extreme it was safer to separate the bladder to its peritoneal fold and freely incise the anterior uterine wall as in vaginal hysterotomy. After weary hours of waiting for effacement and dilatation of the cervix, and with the patient clamoring for relief, the temptation for the average practitioner was great to apply the forceps; but it was his experience that, next to a disregard of aseptic technique, the early application of the forceps, before complete dilatation, was the general practitioner's greatest obstetric sin of commission. Meddlesome midwifery was an apt term for the days before the time of asepsis; helpful midwifery

should now be substituted, but only by those who could invade the birth canal with a technique equal to that of the abdominal surgeon. To stimulate uterine contractions and hasten dilatation, he ordinarily used Voorhees's bag. When a forceps operation was likely to follow, he chose the Pomeroy bag for primiparæ. Its dilatation of the lower part of the birth canal surpassed that of other means for that purpose; its only drawback was the necessity for an anæsthetic to relieve the pain caused by its introduction in the primiparous woman. As a rule, with but few exceptions, it might be stated that in primiparæ four, in multiparæ two, hours should be the maximum limit of the second stage of labor. Any abnormity in mechanism having been corrected and the bladder being empty, when a change in posture from the side to the back, the obstetric pulley, abdominal friction, a hypodermic injection of strychnine, and obstetric analgesia secured by the intermittent administration of ether to relieve pain that might be inhibiting uterine energy-when all these had failed to materially advance the head during an hour of recurring pains, it was his practice to apply the forceps and proceed to a slow and deliberate delivery. For many years it had been his practice to avoid deep anæsthesia at the approach of the third stage of labor, preferring always to conduct the placental stage with the patient fully returned to consciousness.

The prevention of hæmorrhage was, broadly speaking, the proper management of the third, or placental, stage of labor. When uterine inertia had characterized the labor, or when there was a history of bleeding, a hypodermic injection of an aseptic preparation of ergot should be administered just prior to the expulsion of the infant. Immediately thereafter the sentinel hand should be placed on the fundus, but no attempt made to expel the placenta for fifteen or thirty minutes, so long as there was no tendency to relaxation and hæmorrhage. Nature's mechanism for controlling hæmorrhage would be interfered with if massage or the Credé expulsion was too early applied. Manipulation would predispose to bleeding by dislodging clots. The diagnosis of placental separation was not difficult. The retracted uterus steadily rose during the process, and where the placenta had been completely separated, and occupied the lower uterine segment, the fundus was six inches above the symphysis; the uterus was firm and had assumed its natural pear shape, and the length of the extruded part of the cord, from the vulvar opening, had increased from two to four inches. The opposite had obtained when there was concealed bleeding from relaxation of the uterus and partial separation of the placenta. The uterus, soft and globular, steadily rose to a higher and higher level, and the external portion of the cord was diminished in length as it was drawn inward and upward by the receding fundus, to which the partially adherent placenta was attached. When we had thus diagnosticated complete separation, or when partial separation was accompanied by sharp hæmorrhage, then was the time for rapid Credé expression, followed by light massage of the fundus to maintain contraction and retraction. The hooked finger might be required to dislodge the separated have merme segment.

steady traction was made, without twisting, to extract the membranes and the stringy filaments that had broken loose, for they were difficult to handle with the gloved fingers and were best caught in a hæmostatic forceps and slowly extracted. If hæmorrhage occurred and persisted after the too early or unsuccessful resort to the Credé expression, aseptic ergot was injected into the thigh, and the uterus was at once invaded by the gloved hand to remove clots and placental masses and to separate completely a partially adherent placenta. While a hot sterile douche and appliances for the intrauterine pack were being prepared, the vaginal hand should grasp the cervix, occlude it, and push it upward to make forcible traction on the bloodvessels; and the external hand should force the fundus downward and forward over the symphysis, to form an angle in the canal and further stretch and occlude the vessels supplying the uterus with blood. At the same time the ulnar surface of the external hand might compress the aorta and vena cava through the abdominal wall. If the hot intrauterine douche failed to stop the bleeding at once and cause uterine contraction, the uterus should immediately be firmly tamponed with a large quantity of sterilized gauze, the tampon reaching from fundus to vulva. The prevention of bleeding from lacerations of the cervix or vagina required little comment. Preliminary dilatation was the all important prophylaxis.

Inversion of the uterus was practically always preventable. Indentation of the uterine wall by too vigorous manipulation or violent traction on the cord when the uterus was relaxed, and especially the two together figured importantly in causing this accident. When paralysis of some portion of the wall existed, these manipulations were especially dangerous. When partial inversion had been recognized, completion of the inversion could be prevented by desisting from all manipulation of the fundus and the prompt application of an intrauterine pack.

The cardinal principle underlying every means at one's command to prevent lacerations of the birth canal might be expressed in one word, dilatation. Precipitate labor was an extreme type of cases of delivery without preliminary dilatation. It was impossible to prevent those sudden, almost immediate deliveries which occurred only when the passage offered no resistance. For the so called rapid labors characterized by excessive and rapid action of the uterine and abdominal muscles, surgical anæsthesia and manual resistance to the progress of the head until safe dilatation had occurred were the usual means of preventing extensive lacerations.

The prevention of uterine rupture that occurred during pregnancy, from anomalies in the shape or musculature of that organ, so far as his knowledge went, was impossible. It was quite different with rupture during labor; for here a correct diagnosis of the obstacles that prevented the entrance of one or the other pole of the fœtal ovoid into the pelvis and early skilled operative delivery could prevent this dangerous accident. The neglected causes of obstruction caused spontaneous ruptures; the unskilled operator, especially when he attempted a foolhardy version, was the cause of the violent ruptures. Version, attempted when the "contraction ring" was ocularly and palpably at or just below

the umbilicus, was attended with such great danger of rupture that no one should attempt it without great caution and a surgical environment that permitted a safe abdominal section, if a cautious examination under ether showed plainly that even the introduction of the hand was an unwarranted violence.

Lacerations of the cervix were best prevented by securing, naturally or by artificial aid, complete dilatation. In primiparæ early breaking of the bag of waters was a vicious practice, and, when there had been an early spontaneous rupture, the rubber bag gradually distended with water at quarter to half hour intervals accomplished safe dilatation. The partially dilated cervix should never be forcibly pushed back over the head. Before a forceps delivery or extraction of the after coming head, the cervix must be completely and slowly dilated with the bag, manually, or with the most cautious use of metallic dilators, if one hoped to avoid extensive lacerations that often involved the bases of the broad ligaments and the upper third of the vagina. The application of the forceps before complete dilatation, and its dynamic use to complete dilatation, were permissible only to the operator of wide experience, who knew the time required and the dangers incident to this method. Preliminary dilatation of the pelvic floor and vaginal outlet was also the best method to prevent extensive vaginal lacerations. Manual efforts could not be compared to the efficiency of Pomeroy's bag. The tendency of its vaginal portion to be spontaneously extruded from the vagina and to drag the cervix downward could be prevented only by holding it within the vagina during the distention of its vaginal compartment.

As the head was traversing the vaginal canal the mechanism of this stage of labor must be supervised. Rapid extension of the head should be prevented. The handles of the forceps in operative cases must not be elevated too far or too quickly. The long diameter that offered in face presentations demanded cautious flexion even after the chin had passed well beyond the subpubic arch. Forceps rotation in occipitoposterior positions was popular in New York, but even with a solid bladed instrument it added a distinct danger of vaginal injuries. He had never convinced himself that episiotomy could prevent pelvic floor injuries, and consequently never employed it except to enlarge the vulvar outlet when a

sphincter laceration seemed imminent.

The Prevention of Maternal Infection.-Dr. EDWIN B. CRAGIN said that the subject naturally divided itself into three periods of time-pregnancy, labor, and the puerperium. The avenues of infection concerned the genital tract on the one hand and the breasts on the other. Three possibilities of in-fection deserved careful consideration, the use of vaginal douches with unclean nozzles by the patient, marital relations during the last weeks of pregnancy with the husband unclean but not infected, and marital relations during the last weeks of pregnancy with the husband infected with gonorrhœa. The use of the ante partum douche by the obstetrician had been abandoned under ordinary circumstances, on the ground that even with a sterile nozzle there was danger of lowering the protective power of the vaginal canal and perhaps danger of introducing infection from a nonsterile vulva without to the ster-

ile vagina within. Patients should be instructed not to take vaginal douches during pregnancy, save on the special order of the obstetrician and with par-ticular precautions. If during the last month of pregnancy there was danger in vaginal examinations by the obstetrician with cleansed and disinfected hands, there certainly was danger from marital relations with a husband whose habits of cleanliness of the genital organs were far from scrupulous. In many a case of infection following labor could the history be obtained that marital relations were practised even within the last forty-eight hours preceding labor. This held good even with noninfected husbands. It held with infinitely greater force with husbands infected with gonorrhea. If the patient was found to be infected with gonorrhæa during pregnancy, every effort should be made to cure the gonorrhœa, both for her sake and the baby's, before the onset of labor, but with this exception, while the vulva should be kept as clean as possible during the last month of pregnancy by external cleansing, the vagina should be kept a closed canal, and if it was entered by the sterile fingers of the obstetrician, this should be as infrequent as possible consistently with accurate knowledge of the pelvic and fœtal conditions. The low mortality of carefully conducted obstetric cases in the tenements showed that, with the vulva and surrounding parts clean and the physician's fingers and instruments clean, results might be obtained which compared favorably with the statistics of the best maternity hospitals. methods of chief importance, then, were (a) the preparation of the vulva, (b) the preparation of the doctor. The three essentials to a clean vulvar field were an empty rectum, a closely clipped or shaven vulva, and a vulva well cleansed with clean soap and water, the direction of the cleansing being from before backward. The use of sterile rubber gloves was now so universal, and their advantages were so well recognized, that the doctor might regard himself as culpable if he did not avail himself of this additional safeguard against infection. Vaginal examinations should be made as infrequently as was consistent with ascertaining the conditions and progress of the case, and external manipulation through the abdomen should be practised until the knowledge thus gained would make frequent vaginal examinations unnecessary. Since the fact that the vagina was usually more sterile than the vulva was recognized, great care should be taken that, when making a vaginal examination, the labia were separated with the fingers of one hand, so that the fingers of the other hand passed directly into the vagina without carrying infection by contact with the nonsterile vulva to the sterile vagina.

If meddlesome midwifery was bad, negligent midwifery was equally bad, and experience taught that, if material infection was to be avoided, delivery should also be aided before the strength and tissue resistance of the patient were exhausted. The presence of organic material such as portions of placenta, membranes, and blood clots within the uterus so favored the development of sapræmia and perhaps septicæmia that he desired to emphasize the importance of determining at the time of labor that the placenta and membranes had been completely expelled and that the uterus remained so

contracted that blood clots could not accumulate within it. The first object was gained by waiting a sufficient time for the uterus to regain tone before expressing the placenta. This period of waiting at the Sloane Maternity was fixed at twenty minutes from the birth of the child, and during this time the fundus was gently held in the palm of the hand, with just manipulation enough to prevent its ballooning. As soon as the placenta and membranes were expelled, they should be examined carefully to ascertain if they were complete, and if this examination showed the absence of any large portion of either, he believed that infection was avoided by carefully inserting the sterile gloved hand into the uterus and removing the retained portions.

Regarding the use of the post partum douche, he believed that greater safety lay in its omission, save for two special indications, checking hæmorrhage and washing away débris that had been loosened by the fingers. In these cases the greatest care should be observed in having the syringe, nozzle, and solution absolutely sterile. To maintain the contraction of the uterus, there were two measures at command, the administration of ergot and the gentle holding of the fundus until an hour had elapsed from the

birth of the child.

He believed that the use of ergot had a special value as a supplement to, but not as a substitute for, the holding of the fundus. With regard to the repair of the lacerated cervix at the time of delivery, he had seen within the last few years several cases of infection that seemed to be directly traceable to this operation, with its increased manipulation in the vagina and with its interference with uterine drainage resulting from a too great closure of the cervical canal. It was a good rule to suture a lacerated cervix immediately after labor only where there was excessive hæmorrhage. The need of carefully sterilizing the catheter was well recognized, but the ease with which a sterile catheter could wipe off infective material from the vulva and carry it into the bladder seemed to be often overlooked in practice, even if it was known in theory. The only safe way to introduce a catheter in the female was, with the labia separated and the meatus well exposed and cleansed, to pass the catheter directly into the meatus without touching the surrounding parts.

One of the occasional causes of infection in the second week was stenosis of the canal of the uterus with retention of lochia resulting from a flexion of the uterus. While this was more common with an anteflexion than with a retroflexion, still it might occur with the latter, and this tendency to a posterior displacement of the uterus should be warned against by having the patient, after the fifth day, keep off the back for a considerable period each day, lying for a time on one side, then prone, and then on the other side. It was also of value, unless otherwise contraindicated, to favor drainage by having the patient, after the fifth day, use the com-

mode at least once a day.

The prevention of breast infection during lactation depended upon the care of the nipples during pregnancy and the care of the breast and nipples during the puerperium. This implied cleanliness and keeping the nipples free from the crusts which were apt to form as the breasts began to secrete.

The nipples should be bathed night and morning with a saturated solution of borax in fifty per cent. alcohol. If the nipples were retracted, easy nursing and ready emptying of the ducts were favored by having the patient, during the last weeks of pregnancy, gently draw out the nipples with clean fingers at the time she bathed them with the borax solution. The care of the breasts and nipples during the puerperium implied cleanliness, support, and free drainage. In carrying out these indications three propositions should be considered: I. Lack of cleanliness favored infection even with sound nipples, and more so with nipples which were cracked or abraded. 2. Overdistended milk ducts easily became inflamed and infected, especially if the nipples were not sound and clean. 3. Sagging of the breasts during lactation favored overdistention and there-fore infection. The prophylactic treatment consisted in support of the breasts by a properly fitting binder, massage of the breasts if the ducts showed a tendency to become overdistended, cleanliness of the nipples and the baby's mouth, the prevention of cracks and abrasions as far as was possible, and the healing of them so soon as practicable if they occurred. In order to prevent abrasions of the nipple, the baby should not be allowed to remain at the breast longer than five minutes every four hours, and only in the daytime, until the milk was secreted. Between the nursings, the nipple should be covered with a piece of sterile lint smeared with sterile albolene. For the healing of cracks and abrasions, the application of an eight per cent. nitrate of silver solution, followed for a short time by the use of a sterile nipple shield, had proved valuable in his If the nipple continued to be tender and nursing painful, applications of the glycerole of tannin would usually give relief. If mastitis threat-ened, the breasts should be emptied, the bowels emptied, and ice applied to the breasts.

(To be concluded.)

Letters to the Editors.

THE SIGN OF THE RED CROSS.
500 FIFTH AVENUE, NEW YORK,

July 7, 1908.

To the Editors:

Will you not afford space in your valuable journal for a word to our friends in the hospitals of New York State and elsewhere who have been making use of the Geneva, or red, cross as a means of raising funds on "tag days" and similar occasions, in innocent (no doubt) but express violation of the charter rights of the American National Red Cross and of our treaty obligations as a nation?

It is probable that the hospitals are not aware that they are misusing the insignia of the Red Cross, still less that in doing so they are injuring the Red Cross itself. They have found other persons and institutions using the red cross, and doubtless have thought it harmless for them to use it, especially for a purpose more or less like that of the Red Cross. When they learn that the red cross is the common symbol of all army hospital corps and auxiliary Red Cross societies, which protects the

sick and injured and the hospital personnel and material from attack in time of war, and that now, all over the world, it has come to cover and signify this special and official kind of protection, relief and prevention of sickness and injury in war, disaster, and pestilence, they will realize that it cannot be used loosely without having its usefulness seriously

impaired.

Emergency relief, indeed, on the large scale which the Red Cross has to undertake in times of calamity can only be organized through long previous preparation. It is in part as a preparation for its other duties that it has embraced this year what is, perhaps, the greatest mission of all, that of combating tuberculosis, which slays its hundreds where war slays its tens. Preparation is a question of educating and rousing the people to protect themselves. It cannot be done in a minute. Millions of dollars are needed before a tolerable condition of preparedness can be reached. The problem of stopping the terrible drain of life and power is a vital one to America, and the assistance of all her children is needed, not only in the multitude of important special ways of which the hospitals are worthy examples, but in other larger general and more inclusive

Only those concerned with questions of a large and general nature know how difficult it is to secure and hold the popular attention to a subject after the crisis has passed. It is particularly difficult to make our American people realize that war and disaster and pestilence are coming again and again to exact their frightful harvest of death and suffering, unless something is done to check them, and that it is infinitely more merciful (as well as sensible) to take pains for prevention than for belated relief. The need of a symbol which shall recall and summarize to the popular mind what has been done along this line and what remains to be done is plainly apparent. Its significance is what gives it its value. This is why the hospitals like to use the picturesque Geneva cross, and precisely why they should not use it. Every misuse makes for confusion, and the loss through confusion falls ultimately and heavily upon the people themselves, whose organization the Red Cross is.

Our national Red Cross is not, as some people imagine, a private and exclusive society. It is, instead, the whole people organized for the purpose of preventing suffering and loss of life. Everybody—man, woman, or child—may become a member and have a voice in it. It is public and official; one third of the members of the central committee are appointed by the President of the United States, the finances are audited by the War Department, and a report is annually made to Congress. It is linked with the Red Cross societies of forty-two other nations, whose total membership is upward of

five million members.

It may be asked, perhaps, why, with this important rôle, the Red Cross has not been given power to protect itself. The answer is that it has been given such power. By an act of Congress, January 5, 1905, the misuse of the red cross is made a misdemeanor, punishable by fine or imprisonment or both. Although the Red Cross has power to prosecute, it feels it better to be merciful here also. The

abuse of the red cross is not of recent standing. Many persons and institutions are using it in innocent ignorance of the injury they are causing. Moreover, the Red Cross has not until recently made an attempt to protect its insignia. It has depended upon the loyalty of the people. Our people, however, are a busy people, engrossed to a large extent in their own affairs, and something in the nature of a reminder seems to be needed. May I take the liberty of offering it in this present form, and begging especially of the hospitals, which have the interest almost of kinship in the Red Cross, to help secure the latter in its emblem? The Department of Charities of New York, thanks to Commissioner Hebberd, and Bellevue and the Allied Hospitals of New York, have set a splendid example to the hospitals of the country by changing from the red cross to the symbol of Æsculapius, and it is already bearing fruit. Will not the members of the hospital boards, as distinguished and enlightened members of the community, do as much?

H. F. Draper, Secretary, New York State Branch.

Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Health Education League Booklets. Published by the League, 113 Devonshire Street, Boston, Mass.

The Health Education League has concluded its third year of very beneficial work. It is a Boston society (president, Dudley A. Sargent, M. D.; secretary, the Rev. George H. Cate; treasurer, Mr. A. L. Darrow), the aim of which is to educate our people to a healthy living. This is to be done by lectures and booklets. The latter are sold at a nominal price. Fifteen such booklets have been planned for publication so far, and Nos. 1 to 9, 11, 13, and 15 have appeared. They should be widely distributed. If our dispensaries could afford to give some of these printed advisors free to their patients, the benefit derived would be undoubtedly very great. For example, No. 1.—Hints for Health in Hot Weather; No. 2.—Milk; No. 4—Meat and Drink; No. 5—Healthful Homes; No. 8.—The Care of Little Children; No. 9.—The Plague of Mosquitoes and Flies; etc. For our schools, for both teachers and pupils, is well adapted No. 7.—The Boy and the Cigarette.

Le Cancer. Prophylaxie, étiologie, traitement. Par le Docteur C. Sobre-Casas, médecin de l'hôpital Rawson (Buenos Aires). Paris: G. Steinheil, 1908. Pp. 224.

Commissioned by his government to make a report on the existing agencies in Europe and America for the study and control of cancer, M. Sobre-Casas presents in this volume the result of his observations and studies abroad. There are given in considerable detail the resources and efforts of all important institutions in every country working in the campaign directed against cancerous disease, a movement which, in enthusiasm, energy, and hopeful promise, is now probably only second to the similar worldwide warfare being waged against tubercu-

lous disease. The various ætiological theories are intelligently discussed, surgical treatment is properly given the preeminence to which its superiority over all other methods of treatment at present entitles it, and optimistic views are expressed as to the outcome of the widespread interest now being taken in the question of the control of this scourge. M. Sobre-Casas's volume constitutes a substantial addition to the literature of the subject which will be appreriated by every student of malignant disease.

An Aid to Materia Medica. By Robert H. M. Dawbarn, M. D., Professor of Surgery and of Surgical Anatomy, New York Polyclinic Medical School, etc. Fourth Edition, Revised and Enlarged by Edd V. Delepher, M. D. New York: The Macmillan Company, 1908. Pp. xi-338. (Price, \$1.75.)

This book presents in a short space and tabular form all the drugs and preparations recognized by the present pharmacopæia, with a list of the newer unofficial drugs and remedial agents. It is a carefully prepared manual, to be used for its instructive as well as its reference value.

Miscellany.

A Revision of the International Classification of Causes of Death .- Dr. Cressy L. Wilbur, the chief statistician of the Bureau of the Census, has issued the following circular, dated June 2, 1908:

DEAR DOCTOR—The International Classification of Causes of Death, which is intended for the purposes of morbidity and hospital returns as well as for mortality statistics, will be subjected to its second decennial revision next year. This system, formerly known as the "Bertillon system," was recommended by a committee of the International Statistical Institute during its session at Chicago in 1893. It was urgently recommended for adoption by the American Public Health Association, representing the sanitary authorities of Canada, Mexico, and the United States, in 1898. In the first revision, held at Paris in August, 1900, representatives of twentysix countries participated. It is employed by the United States Bureau of the Census, by all registration States, and by nearly all registration cities in the United States. Every country in North and South America has adopted it, and it is used by Japan, and by France, Spain, Holland, Belgium, Greece, Bulgaria, and other European countries. It has also recently been adopted, after careful comparison with the system formerly in use, by the Bureau of Census and Statistics of the new Commonwealth of Australia.

At the recent meeting of the American Medical Association at Chicago, the House of Delegates unanimously resolved 'That the International Clas-sification of Diseases and Causes of Death be recommended for all official morbidity and mortality statistical reports." A special committee, whose chairman is Dr. Frank P. Foster, of New York, is preparing recommendations for submission to the International Commission of Revision, and committees have been appointed by the various sections of the association and by national organizations, such as the American Academy of Medicine, the American

Medicopsychological Association, and others, to cooperate with the association's committee. The subject of classification will be made a special topic at the approaching session of the Section in Vital Statistics of the American Public Health Association. to be held at Winnipeg, Manitoba, August 25 to 28, 1908.

It was proposed in the resolutions adopted by the American Medical Association at Chicago that inquiry be made as to the possibility of holding the meeting for revision at Washington in 1910 in connection with the International Congress of Hygiene and Demography, but the preliminary announce-ment just issued by Dr. Bertillon, at the request of the Ministry of Foreign Affairs of the French Government, indicates that the year 1909 has been chosen, largely to facilitate the use of the revised classification in connection with the mortality statistics of the census year 1910 in the United States. This action should be greatly appreciated, and all registration officials, health officers, hospital physicians, and the profession generally should cooperate, so that the results of the revision will be thoroughly satisfactory for use in this country during the next ten years. Many suggestions from American physicians were incorporated in the first revision, but the progress of medical science and the test of practical use will indicate changes that are desirable. The system may be examined in the annual reports on mortality statistics published by the Bureau of the Census, as well as in the registration reports of many States and cities. A copy of a pamphlet on Relation of Physicians to Mortality Statistics, containing an outline of the classification, will be sent by the director of the census to any physician upon request, and I shall be pleased to receive any suggestions for the revision of the classification, which I will submit to the cooperating committee and to the International Commission.

CONSTITUTION OF COMMITTEES.

lThe General Committee of the American Medical Association on Nomenclature and Classification of Diseases was authorized to continue its work by unanimous vote of the House of Delegates on June 3, 1908, and, according to the terms of the original resolution under which it was constituted, it is desirous of cooperating with representa-tives from other national organizations interested. The following list of committees includes those appointed in the short interval up to June 24, 1908. It is hoped that other organizations, whose meetings take place later in the year, will appoint representative committees, and that physicians generally will aid by practical suggestions.]

AMERICAN MEDICAL ASSOCIATION

GENERAL COMMITTEE ON NOMENCLATURE AND CLASSIFICATION

BLACKWELL, E. M., Surgeon. Commissioned a surgeon from March 4, 1908.
 COLTES, F. X., Assistant Surgeon. Detached from the Connecticut, and ordered to report to the commander, third squadron, Pacific Fleet, for duty.
 EYTINGE, E. O. J., Assistant Surgeon. Detached from the Concord and ordered to the Illinois.
 FISKE, C. N., Passed Assistant Surgeon. Ordered to the naval recruiting station. Boston Mass, and to adding the control of th

naval recruiting station, Boston, Mass., and to addi-tional duty in attendance upon officers of the Navy and the Marine Corps residing in Boston not otherwise provided with medical attendance.

FLINT, J., Assistant Surgeon. Detached from the Wil-mington and ordered to the Connecticut.

Hugans, M. E., Assistant Surgeon. Detached from the Illinois and ordered to report to the commander, third squadron, Pacific Fleet, for duty.

Mann, W. L., Jr., Acting Assistant Surgeon. Appointed

an acting assistant surgeon from July 1, 1908.

B. E. H. H., Assistant Surgeon. Detached from the Naval Hospital, Cavite, P. I., and ordered to Washing-

SMITH, F. W., Assistant Surgeon. Detached from the Wisconsin and ordered to report to the commander,

Wisconsin and ordered to report to the commander, third squadron, Pacific Fleet, for duty.

STALNAKER, P. R., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from May 3, 1908.

STEELE, J. N., Medical Inspector. To be placed on the retired list on September 18, 1908, after the completion of thirty years' service, in accordance with a provision contained in the naval appropriation act of May

T3, 1908.

WHITE, E. C., Assistant Surgeon. Relieved from further duty in Cuba and ordered to comply with the Navy

Department orders of May 29, 1908.

Births, Marriages, and Deaths.

Born.

KENNEDY.—In Washington, D. C., on Monday, June 22d, to Dr. Robert M. Kennedy, of the Medical Corps of the United States Navy, and Mrs. Kennedy, a daughter.

VAN METER.—In Lexington, Kentucky, on Tuesday, June 30th, to Dr. Benjamin F. Van Meter and Mrs. Van Meter, a son.

BLUMENTHAL-FELDSTEIN.-In Philadelphia, on Tuesday, June 30th, Dr. Adolph Blumenthal, of Pittsburgh, and Miss Ida Feldstein.

JACKSON—SEDGWICK.—In New York, on Wednesday, July 1st, Dr. Egerton S. Jackson and Mrs. Mary Elizabeth Sedgwick.

Satterwhite—Martin.—In Great Neck, Long Island, on Tuesday, July 7th, Dr. Preston Satterwhite, of New York, and Mrs. Florence Brokaw Martin.

Shehan—Huston.—In Louisville, Kentucky, on Tuesday, July 7th, Dr. John N. Shehan and Miss Lydia Lee Huston.

WICKES—APPEL.—In 'Fort Russell, Wyoming, on Wednesday, July 8th, Dr. George Lewis Wickes, of the Medical Corps of the United States Navy, and Miss Marjorie Appel.

BARNES.-In Oxford, Connecticut, on Sunday, July 5th,

DARRIS.—III OATOIG.
Dr. Lewis Barnes, aged eighty-four years.
BRADLEY.—In Kansas City, Missouri, on Thursday, July
2d. Dr. Zarilda P. Bradley, aged forty-five years.
COYLE.—In New York, on Friday, July 10th, Dr. Felix

H. Coyle.

Dodge.-In Lost Cabin, Wyoming, on Monday, July 6th, Dr. George Dodge.

Drescher.—In Brooklyn, on Tuesday, July 7th, Dr. Maximilian Frederick Charles Drescher, aged forty-nine years. Flannery.—In Philadelphia, on Thursday, July 2d, Dr.

FLANNERY.—In Finiadelpina, on Inursday, July 2d, Dr. Henry Flannery, aged thirty-one years.

GLEASON.—In London, England, on Friday, July 3d, Dr. C. Campbell Gleason, of New York.

HEAVRIN.—In Owensboro, Kentucky, on Tuesday, June 30th, Dr. J. P. Heavrin.

HINES.—In Raleigh, North Carolina, on Wednesday, June 24th, Dr. J. M. Hines, aged seventy-two years.

HOFFMAN.—In Jersey City, New Jersey, on Wednesday, July 8th, Dr. James Hoffman.

July 8th, Dr. James Hoffman.

HUTTON.-In Haines Corners, New York, on Tuesday, July 7th, Dr. Allan Clarke Hutton, of New Brunswick, New Jersey, aged sixty-seven years.

Lypston.—In Chicago, on Monday, July 6th, Dr. Lames.

Lydeton,—In Chicago, on Monday, July 6th, Dr. James A. Lydston, aged forty-seven years.

Monroe,—In Monroe, Wisconsin, on Monday, July 6th, Dr. William Monroe, aged ninety years.

Shaw.—In New Bedford, Massachusetts, on Thursday, July 2d, Dr. John C. Shaw, aged fifty-one years.

Sterling.—In Fairmount, West Virginia, on Tuesday, June 30th, Dr. A. W. Sterling, aged fifty-nine years.

Stoutt.—In Camden, New Jersey, on Friday, July 10th, Dr. Daniel M. Stout aged eighty-type years.

STOUT.—In Camen, sew Jersey, on Friday, July Comp. Daniel M. Stout, aged eighty-two years.
Tillotson.—In Chicago, on Thursday, July 2d, Dr. George K. Tillotson, aged fifty-eight years.
Wittins—In Hammonton, New Jersey, on Monday, Inno. 20th, Dr. W. George Wilkins.

COMPLICATING GRAVES'S DISEASE.*

BY CHARLES G. STOCKTON, M. D., AND A. E. WOEHNERT, M. D., Buffalo, N. Y.

Mrs. A. V. C., aged forty-three, married, born in Sweden. Family history good. She had had six living children and two miscarriages, one at six weeks, a second at ten weeks. She always enjoyed fairly good health. During the summer of 1904 she had slight ædema of the lower limbs. In December, 1904, she noticed that she tired easily, felt more or less exhausted, and had some cough and expectoration. Early in 1905 she noticed swelling of the neck and some protrusion of the eyes; she did not seem particularly nervous, nor did she give a history of much loss in weight. She was first seen in June, 1905. At this time she presented the typical facies of Graves's disease. The expression of her face, with its marked exophthalmus, was striking. Her appetite was good, her bowels had been constipated since November, she had been sleeping poorly of late; there was no history of any digestive disturbance, and she had no

Physical examination: Heart apex in the sixth space, a little to the left of the normal position. First sound lacked in muscular quality and was accompanied by a systolic bruit which increased in intensity toward the base of the heart; second sounds were well balanced and of normal intensity; the lungs were clear; the liver dulness extended from the sixth rib to the margin of the ribs; the splenic dulness was not increased; the pulse was 100, of poor quality; the thyreoid gland was much enlarged; a loud systolic sound was heard over both lobes, also heard over supraclavicular and infraclavicular regions; reflexes were normal; there was some nystagmus; von Graefe's sign present; the urine was dark amber in color, specific gravity was 1.030, no albumin, no sugar, indican was present, no casts were found.

A diagnosis of Graves's disease was made, and the patient was placed upon thyreoidectin, and was advised to rest. She returned to her home in a neighboring city, and was not seen again until September 9th. Her condition was now distinctly worse. There was more shortness of breath, now distinctly worse. Incre was more shortness of breath, the pulse was 130, and the temperature 98.6° F. Upon examination the heart was found dilated, there was a distinct gallop rhythm. Examination of lungs showed flatness and absence of breathing over the left chest. The liver dulness extended from the sixth rib to the umbilicus; the abdomen was large. Patient entered the General Hospital on September 14, 1905.

September 15th. The left chest was aspirated and 1,210 e.c. of brownish serous fluid were removed. Examination of the fluid: Specific gravity, 1.015; albumin present; no sugar; blood present; some endothelial cells; no bacteria

September 16th. Patient felt easier; physical signs showed harsh breathing over the left chest and a coarse friction rub. There was cough, and frothy mucopurulent sputa was raised.

September 18th. Liver dulness extended from upper border of the fifth rib to two inches below the umbilicus, and was ten inches in width.

*Read before the Association of American Physicians, Washinston, D. C., May 13, 1968.

September 21st. Cardiac dulness extended one and one quarter inches to the right of the median line in the second space, and two inches to the right of the median line in the fifth space; left border of the heart at third rib was three inches to the left of median line, six and one fourth inches in the sixth space. The heart action was irregular; no friction; no endocardial murmurs were heard; the first sound was valvular in quality.

September 26th. White cells, 9,400; hæmoglobin eighty

per cent. Examination of the chest showed fair resonance

October 5th. Patient was nervous and emotional. She had a chill and temperature of 101° F. There was unusual

prominence in the right subclavicular region.
October 6th. Temperature, p. m., 102° F.; patient was excitable; right shoulder and regions above and below F.; patient was

Cavicle were more prominent and reddened.
October 8th and 9th. Some pain and redness in the right shoulder and clavicular region.
October 10th. Right arm was larger in circumference than the left and was somewhat painful.
October 11th. Circumference of the left arm, six inches

above the external condyle, was eight and a quarter inches; right arm, same region, eleven and three fourths inches. Left forearm, two inches below the external condyle, was eight and a half inches; right arm, same region, ten inches. There was a feeling of bogginess; there was pain on deep pressure.

pressure. October 12th. Examination of the heart showed first and second sounds of equal duration; no murmur; from the fifth space to the third rib, left of the sternum, reduplication of the second sound was heard. The liver dulness extended from the fifth rib to one and a half inches above the umbilicus. The blood showed a leucocytosis of 8,460; hæmoglobin eighty per cent.

October 14th. Swelling extended down to the right wrist; there was a small nodular mass under the axilla,

painful on pressure.

October 15th. Tissues generally ædematous on the right side of the face and upper part of right thorax.

October 20th. Right arm, six inches above the external condyle, was fourteen inches in circumference; left arm, condyte, was norteen menes in circumsterice; left arm, two inches below external condyle, twelve and one quarter inches; left, same region, eight and one half inches. Right wrist, level with styloid, eight and one quarter inches; left, six inches. The fingers of the right hand were more cyanotic than the left; the face was more edematous and cyanotic on the right side than the left. The superficial veins in the right side of thorax were prominent and engorged. The right side of the chest became still more prominent. There was side of the chest became still more prominent. cedema at the bases of both lungs, and there was fluid in the right pleural cavity

October 26th. One hundred c.c. of straw colored fluid

were removed from the chest.
October 20th. Œdema more marked; extremities were cyanotic; respirations frequent and labored; the superficial veins of thorax were more dilated.

October 30th. Sixty-five c.c. of slightly turbid fluid were withdrawn from the right chest. Patient was very weak

and exhausted.

November 2d. Four hundred and fifty c.c. of fluid were

withdrawn from right chest.

November 3d. Edema of the chest and face somewhat less marked. The veins, especially in the back, were much enlarged. November 4th. Two thousand c.c. of fluid were withdrawn from the right pleural cavity.

Pericardium slightly thickened; heart was slightly enlarged, but not increased in weight. The valves were normal, save of the mitralis, which were somewhat thickened. Aorta showed no sclerosis. The superior vena cava and both innominate veins were firm and hard. The superior vena cava and right innominate contained a mass of pinkish, grey material which could not easily be stripped off. The left innominate was not wholly occluded. There were some adhesions in both pleural and in the pericardial cavities. The right lung was small and compressed by fluid. The liver was large, firm, the lobules well marked on section, and the surface irregular. The thyreoid was much enlarged. The eyes receded in their sockets and were covered with lids

ered with lids.

Post mortem diagnosis: Exophthalmic goitre, thrombosis of vena cava and right vena innominata, also practically complete thrombosis of the left innominate vein.

November 5th. Jaundice developed, and the patient gradually became comatose, and died November 9, 1905.

Autopsy: Nine hours later, made by Dr. N. G. Russell.

The case presented the features of a very acute form of Graves's disease, the course extending from January, 1905, to her death, November, 1905. From her second visit in September until her death, the general features were more those of circulatory failure than those due to disturbance of the nervous system. There was an occasional rise in temperature before the signs of venous thrombosis appeared. The thrombus evidently started in the right innominate vein. For a day preceding the formation of the thrombus there was a rise in temperature. October 5th, the day of onset, she had a chill, and, locally, pain, tenderness, and swelling above the right clavicle.

The subsequent course was one of progressive obstruction to the venous return, as evidenced by the increase in œdema of the arm and face, the enlargement of the superficial vessels, and the current flowing downwards to communicate with the inferior vena cava. Her temperature immediately after a chill rose to 102° F., and then gradually declined, to reach normal two weeks later. Welch, in an article published in 1900, was able to collect twenty-eight cases of thrombosis in heart disease, of which the superior vena cava was thrombosed partially or wholly in six. The most common starting point was in the left jugular bulb, or left external jugular vein, or left innominate or subclavian vein. The left side was affected in twenty-two out of twenty-four cases, of which fifteen were unilateral and seven bilateral.

In searching for a cause for the thrombosis in this case, three hypotheses might be entertained:

First. The pressure of the enlarged heart might have been sufficient to obstruct the venous return. Pressure of the left auricle in mitral disease may possibly induce obstruction.

Second. The change brought about in the blood in Graves's disease renders the affected individual more liable to infections of various kinds. Although there was no leucocytosis at any time in this case, there was rise in temperature, and there may have been a septicæmic condition developed secondary to a decrasia

Third. At the autopsy the fasciæ covering the veins appeared to be tense and thickened, and with venous engorgement resulting from failing circulation, might give rise to obstruction sufficient to favor thrombosis. Thrombosis of the superior vena cava complicating Graves's disease appears to be unique. We have been unable to find another case in the favorating.

THE SUPPOSED EVILS OF EXPERT TESTIMONY.

By F. X. Dercum, M. D., Philadelphia,

Professor of Nervous and Mental Disease, Jefferson Medical College; Neurologist to the Philadelphia Hospital.

At the meeting of the Medicolegal Society of Philadelphia, held on April 28, 1908, in an address on expert testimony, I expressed in substance the following views. I have been prompted to formally publish them for these reasons: First, much misunderstanding exists especially on the part of physicians as to the nature of expert testimony and as been said from time to time of the "evils" so called of expert testimony; and thirdly, because every now and then correctives for these supposed evils are proposed which I believe to be very unwise. Among these I must include some proposed by my friend, Dr. George W. Jacoby.

It will be best to begin by a brief statement of facts. Thus, expert evidence differs from ordinary evidence; it is essentially opinion evidence. The testimony of nonexpert witnesses consists in the recital of facts-of facts seen, heard, or otherwise perceived by them. The testimony of an expert consists in the giving of opinion. The opinion may be based, first, upon facts observed by the expert himself, secondly, upon facts testified to by others, and, thirdly, upon facts embodied in a hypothetical question. The facts observed by himself are of course a part of the expert's testimony in chief, and logically precede the giving of his opinion. Quite commonly these facts are technical in character and require for their determination technical training. Essentially, however, the position of an expert is that of a witness who draws inferences from facts presented, such inferences being justified by the special knowledge which he is supposed to have. We are next confronted by the question "What

constitutes an expert?" Under our laws-and I believe the provision to be a wise and just one-any witness may qualify as an expert, but the fact that a witness really possesses expert or technical knowledge must be clearly presented by counsel. When counsel fail to do so, the court may so interrogate the witness introduced as an expert as to place his qualifications clearly and unmistakably before the jury. When counsel do their duty, there is no danger of the testimony of an improperly qualified person having undue weight. If an improperly qualified person is placed upon the stand, one or two questions by counsel or court at once reveal the truth. For instance, in a trial in which the question at issue was that of insanity, a physician took the stand and made the general statement that he had given a great deal of attention to the subject of insanity. When requested to make a specific statement as to his experience with insane patients, he said that he had been a resident physician in a large asylum for the insane which contained many hundreds of patients. Questioned as to the duration of his service, it transpired that he had been at the hospital only a few weeks and then merely as a substitute. It need hardly be added that the jury gave as little weight to his testimony as it deserved.

Congre W. Jacoby, Psychiatric Expert Exidence in Criminal Proceedings Vene York Medical Journal, March 7, 1908, p. 431.

An expert witness is one supposed to have special knowledge of the subject under investigation and the jury are quite able to correctly judge of this fact. They hear of the opportunities which the witness has had for acquiring special knowledge, namely his experience in institutions, the positions which he holds or has held, the original papers, monographs, or books that he has written, or investigations that he has conducted. They have no difficulty in taking a proper measure of the man before them. They readily perceive that Dr. A., a general practitioner, is hardly as competent as Dr. B., a trained ophthalmologist, to give an opinion involving a question of injury to an eye. They readily understand that Dr. C., a surgeon, is not as capable of forming a judgment on a question of insanity as Dr. D., for many years an asylum man. Further, they even form quite correct judgments of the relative merits of men pursuing the same departments of knowledge. The jury are impressed as are others by age, wealth of experience, general reputation, and last but not least, the personality of the witness-whether he is honest, whether he is telling the truth as best he can.

It is quite the fashion to speak—both loosely and inadvisedly. I am convinced—of what are called the "evils" of expert testimony. Physicians in particular are in the habit of so expressing themselves, and not infrequently they are physicians who have testified as experts. My own observations in the courts, extending now over a quarter of a century, have convinced me that these evils are greatly exaggerated; and further I am convinced that such evils as may exist are due not to methods of legal procedure, but to the expert himself. The expert is human and not always blessed with a judicial temperament,—the faculty of making cold scientific abstractions. Not infrequently the circumstances of a case are such that the expert becomes interested. Almost involuntarily, often subconsciously, sentiment or emotion is aroused. Little by little a personal bias is acquired, and, though this may be acquired unconsciously, it is none the less prejudicial to the expert's testimony. Not infrequently he thus becomes an active partisan of the side for which he is called, and often reveals his bias both in his manner and in his language. Indeed, first among the evils of expert testimony, I would place the bias of the expert.

The expert frequently mistakes the nature of his function. Instead of regarding himself merely as a witness in the trial of a case, he regards himself as and assumes the rôle of counsel. That such an attitude leads unavoidably to distortion of facts and to malpresentation of evidence and that it hopelessly impairs the position of the expert, goes without saying. The expert has, it is true, a function to perform in addition to giving his testimony upon the witness stand, but this does not consist in his trying the case. His proper function begins long before the trial and consists in the discharge of a duty which he owes to the counsel employing him. Just as soon as an expert is in possession of the scientific facts of a case and has formed an opinion, he should present both facts and opinion to counsel. The opinion should be frank and full without regard to the contention of the side employing the expert. If the opinion is such that counsel

find it unfavorable, counsel may determine upon an entirely new course or may abandon a given line of prosecution or defense; or may, perhaps, dismiss his expert and employ another, which he has a perfect right to do. If the opinion is favorable, it should, in any event, be presented in such a way that all of the facts, whether favorable or unfavorable, are presented with equal force. Such a course is the only right course, it is demanded in simple justice to counsel himself. The latter should be in full possession of the unfavorable as well as the favorable facts of his case; besides the expert by taking into consideration all of the unfavorable as well as the favorable facts is able to formulate an opinion so secure as to be unassailable. This is the only logical course, it is the only proper and the only safe course. Everything depends upon the initial honesty of the expert in his conference with counsel employing him.

After having formed his opinion, a cautious and conscientious expert will rearray the facts in his mind and see how they would favor an opposite conclusion than that which he has reached. He should remember that an opposite conclusion may be advocated by opposing experts. Critically reviewing the case will inconceivably strengthen the opinion to which he arrives because it will eliminate all points of doubt and weakness. If a certain opinion is justified, surely it ought to be able to withstand the expert's own criticism, let along the adverse criticism of opposing experts and the cross examination of the opposing counsel.

Difficulties arise due to the ignorance of witness as to the nature of evidence both lay and expert. The professor called from his laboratory or the doctor from his practice forgets too often that the court room is not a lecture room or a consultation The doctor's statements upon the witness stand should be confined to a mere recitation of facts and of logical deductions based upon these facts, never to generalizations or to the citations of illustrations which may or may not have a bearing upon the case, and, least of all, to the presentation of facts which he has not himself observed as existing in the present case. It is true that a physician cannot testify upon the stand very many times without sooner or later gaining some idea of the nature of the facts to which he should testify and the nature of the opinions which it is proper that he should express. Much confusion, however, would be prevented if counsel would occasionally give physicians instruction upon this important matter. Not infrequently I have seen the medical witness, because of repeated objections by the opposing counsel or because of repeated warnings by the court become so confused and so disturbed as to forget the essential parts of his testimony or for other reasons to fail to testify to facts to which it would have been proper for him to testify. On more than one occasion I have known the testimony of the expert through lack of this precaution to be so much impaired as to be of very little value.

Difficulties will, furthermore, arise in expert testimony, because the expert is faulty in his method of presenting his testimony. Two glaring errors are commonly noted, first, an absence of system or of method, secondly the befogging of the facts by the use of technical terms. The testimony should be

presented in as systematic a way as possible. General facts should be stated first, special facts subsequently. In the presentation of the facts, he should realize at once that he can testify only to such facts as are objective in their nature. Thus, in a suit for personal injuries, the expert can testify to such objective symptoms as posture, gait, the presence of scars or physical deformity, the reaction of the patient to various tests, the condition of the circulation, of the surface of the body, of the various special organs, or of other facts evident to his, the expert's, senses. There are other facts which come to his knowledge in the course of his investigations to which he cannot testify; these are the so called subjective symptoms. They constitute facts of which the patient alone can be conscious, which the patient alone can feel, of which he alone can be aware by actual knowledge. However, while the expert cannot testify to subjective symptoms, it is perfectly proper for him to add, after a full presentation of the physical facts, that, in addition to the facts observed, he received a statement of subjective symptoms consonant with the symptoms observed by himself. There is another group of symptoms which, though objective in their nature, are also usually beyond the personal knowledge of the physician — phenomena which he himself has not or perhaps cannot observe and has no means of verifying; among these are restlessness at night, frequency of micturition, menstrual disturbances, or perhaps loss of appetite or the condition of the bowels. Of course, if both the subjective symptoms and this group of nonverifiable symptoms have been testified to by the plaintiff, the expert may take them into consideration in forming his opinion.

In regard to the use of technical terms, it cannot be too strongly insisted upon that their employment is as objectionable as it is usually unnecessary. There are very few scientific statements which cannot be rendered into language so simple that the ordinary layman can comprehend them. Especially is this true of the injuries presented by plaintiffs in damage cases and of the mental symptoms in cases of insanity. Every now and then the testimony of an expert is made worthless by the use of technical terms which obscure and do not elucidate. Further, the expert may also be subjected to frequent and annoying interruptions both by counsel and court, who may direct him to use language which the court and jury can understand.

In testifying to questions of insanity, the statements should also be systematic. The statement should embrace the place and date of the examination, the names of those who were present, the greetings if any exchanged with the person under examination, the demeanor, the conduct of the latter, the things that he said and did, his answers to questions, a statement as to the existence of hallucinations, delusions, and other mental symptoms if present, and finally an enumeration of the various physical signs.

In will cases it is best for the expert to confer with counsel in the preparation of the hypothetical question usually necessary. The expert is rarely a witness of fact; that is, he has rarely had the opportunity of examining the testator during the latter's

lifetime. The hypothetical question should consist of a simple recital of the facts presented by the history essential to establishing either the sanity or insanity of the testator. As a rule the question is uselessly and absurdly long, so long indeed that the jury will not and, indeed, cannot follow it; there are but few cases in which a condensed summary of the facts is not possible. Facts of but slight significance, of but little relevancy to the issue, had best be omitted; first because they are not necessary, and secondly because they are a source of weakness in giving an opportunity for a cross examination which diverts the attention of the jury and befogs the issue. In replying to a hypothetical question, it is usually merely necessary for the expert to reply in the affirmative or in the negative without making any qualifications. However, if a hypothetical question has been prepared by opposing counsel, a reply in the affirmative or negative may be possible, but usually qualifications are necessary.

This leads me to consider the conduct of the expert during cross examination; first as to his manner. He should be as open and as frank in his replies to the questions asked by the cross examiner as to the questions proposed by his own counsel. He should avoid any undue reserve or even the appearance of hedging, for the latter always gives rise to the idea that the witness is more or less biased. The answers should be brief and whenever possible consist of a simple affirmative or negative. qualification is necessary, this should be stated in as simple and as brief language as possible, though as fully as necessary. The expert witness should bear in mind that he is not the counsel in the case, and that he has nothing to do with the outcome. His answers should be scientifically accurate. counsel employing him will usually ask in redirect examination such questions as will tend to clear up or reaffirm points which the opposing counsel may have in cross examination obscured, minimized, or perhaps distorted.

These considerations show, I believe, first, that the "evils" of expert testimony are not as great as supposed, and, secondly, that when present they are in large degree due to the experts themselves.

However, it will be said that there is one great evil which I have not touched upon, namely, the differences of opinion of opposing experts. It is not so much the members of the bar or the courts, but physicians themselves who keep alive this reproach, and they do so, I believe, from an entire misconception of the facts. In the first place, in a very large number of cases, notably in suits for personal injuries, the differences of opinion regarding the actual findings are usually slight; it is only as to the outcome that much divergence of opinion may be noted, and here differences of opinion are frequently entirely legitimate. So it is with questions of mental disease. The differences of opinion are usually not as to the actual findings, but merely as to their interpretation. Usually the questions upon which experts divide are as to whether the findings do or do not justify the diagnosis of insanity, and here again differences of opinion may arise which may be perfectly legitimate. Particularly is this true when we reflect that a very large number of the criminals and other persons whose sanity is the subject of in-

quiry really constitute borderland cases. Furthermore, cases are constantly met with into which litigation does not enter, concerning which doubt arises and concerning which physicians differ. Note, for instance, the lucid cases of melancholia which some physicians refuse to commit and others insist upon committing to institutions. In other words, experts may differ, differ legitimately and honestly, and the difference is usually about borderland questions; and, after all, it is the function of the jury to decide these, and in the observation of the writer the decision of the jury is usually in accord with justice and with common sense. In every department of knowledge similar differences of opinion are developed. The very judges upon the bench differ from each other; they not infrequently hand down dissenting opinions, and the upper courts reverse the lower. Indeed, I am credibly informed that in the highest tribunal of the country, the Supreme Court of the United States, dissenting opinions are handed down in a large percentage of cases. Quite frequently the opinions are in direct opposition to each other, differing upon such fundamental questions as to what is and what is not constitutional, or upon other matters which to the lay mind seem equally elementary and concerning which, according to lay ignorance, there should be no differences of opinion. The facts become still more impressive when we reflect that the members of the tribunal are experts of the highest order and whose honesty and integrity stand on a plane equally high with their learning. Again, the expert opinions of the courts are upon cases stated, and the differences arising have to do with the interpretation of facts, with the application of principles, with divergent points of view. If it is perfectly normal for differences of opinion to arise among these highest of experts, it cannot be surprising that a similar condition obtains when the questions are medical,-when the facts are less definite, less readily determined, when of necessity the personal equation plays a larger rôle, and when there must be a greater range of individual interpretation. And yet I venture to say, in spite of the impression to the contrary, that the differences of opinion obtaining among medical experts are on the whole no more frequent and no more divergent than those obtaining in the high tribunals.

It is obvious that no plan can be devised which will do away with differences in expert opinion. As long as men are honest these differences will exist. An expedient devised long ago has created a body whose special function it is to weigh, reconcile, or cancel these and other differences in testimony, namely, the jury. The expert should remember that he is not the jury, no more than he is the counsel or the court. He is simply a witness whose busi-

ness it is to tell the truth as best he can.

What shall we say as to the proposition occasionally advanced as to the appointment of experts by the courts? This proposition has been repeatedly advanced by Dr. J. N. McCormack, of the American Medical Association, in his talks before the

"In this connection, the address on Great Dissenting Opinions, delivered by the Hon, Hampton L. Carson on August 22, 202 before the American Bar Association, will prove most interesting teaching.

county societies, and has only recently been affirmed by Dr. George W. Jacoby, of New York. To me it seems incontrovertible that the appointment of an official expert by the courts would be a very serious menace to justice. Who is to select the experts? It takes an expert to decide who are experts. Shall the judge, who is a layman in medical matters, make the decision, or shall it be a civil service appointment; if so, who are the experts to examine the experts? Again, it is a matter of common experience that public appointments soon become the play and spoil of politicians, and the danger would be that sooner or later the expert would be a person of the second rank or no rank at all. Finally, even if a man of high standing was appointed, that fundamental right which belongs to both plaintiff and defendant to call such witnesses as can give testimony concerning the matter at issue, would lead to the calling of additional experts by either side. The latter might be men of equal or even greater standing and prominence than the official expert, and notwithstanding would probably have their opinions outweighed, because the court's expert bore the stamp of official appointment. Dr. Jacoby proposes that the expert be especially trained at college; that this training terminate with a special State board examination, and that a special degree of "physician to the courts" should be bestowed. Dr. Jacoby knows full well that expertness cannot be acquired in any training given by any college, no matter what its curriculum. Dr. Jacoby knows as well as I that expertness in nervous and mental diseases is the result of the slow accretion of years. It demands years of close contact with large masses of clinical material, constant observation, and worldwide familiarity with the literature. Surely he will not maintain that such a condition can be brought about by a college curriculum, even if, as he proposes, this curriculum should be followed by clinical psychiatric work in a State hospital. In short, experts cannot be made, neither by the examination of a State board, nor by the fiat of the court.

Upon one point and one point only do I agree with my friend Dr. Jacoby, and that is as to the wisdom of committing, in doubtful mental cases, to State asylums for observation. The opportunities for the detailed study of a case would under such circumstances be greater and more satisfactory than can be obtained in a prison; as to the legal propriety of such an expedient I have no opinion. It is, further, the only expedient I would borrow from the Germans; for the rest I would be quite content with

English law.

In conclusion, I may repeat that I am quite convinced that the so called evils of expert testimony have been greatly exaggerated; that many that do exist can be properly attributed to the expert himself and not to the attorneys nor to the courts; and, finally, that the differences of opinion shown by experts do not constitute an evil properly speaking; if so we must equally, perforce, speak of the evils of the supreme court, an institution upon which depend the stability and permanence of the republic

1719 WALNUT STREET.

Loc. cit.

EXPERT TESTIMONY AND THE ALIENIST.

BY WILLIAM A. WHITE, M. D., Washington, D. C.,

Superintendent of the Government Hospital for the Insane.

It takes some courage to write on this subject at this time when the press, both medical and lay, have but so recently been surfeited with it, and I would not presume to do so did I not think that the general impression created by these writings has been wrong and that there was, after all, something still to be said on this much misunderstood topic.

The particular aspect of the situation which seems to me worthy of comment, because I believe it has failed absolutely of comprehension, is a somewhat remarkable one. While there has arisen on every side a wholesale condemnation of expert evidence in general and the expert witness in particular, and while much of the criticism has arisen from the medical profession itself, nevertheless that profession has nowhere found a champion, but, quite the contrary, appears by a supine acceptance to acknowledge the truth of the criticism against it without so much as a murmur in its own defense. Such an attitude must either have arisen out of a humility that smacks of cowardice or be the result of a complete lack of comprehension of the situation in the large.

Probably the explanation rests to some extent in both of these reasons. While humility is an element in cowardice to the extent that it is the very opposite of that spirit of aggressiveness and self assertiveness that goes with courage, it must not be lost sight of that it frequently is the surface attitude of an intense egotism that seeks thus an expression of self righteousness, and is the not infrequent tool of that well known mental state comprehensively but not elegantly expressed by the term "sour grapes." Professional jealousy is not unknown even among the doctors, and the specialist who is not "called" to give his opinion and to receive large fees therefor, can well afford to decry the lack of morale in his more fortunate brother. In fact, in so doing he is but obeying a physiological law, and, in the language of modern psychiatry, but developing a "defense reaction," so that he may spare himself the discomfort that comes from emotions that find no means of outlet. Less technically he "vents his spleen," thus relieving the tension, so that he may proceed with the day's work in a spirit of calm.

That a lack of adequate comprehension of the problems of expert testimony and criminal law is at the bottom of much of the controversy is shown by the nature of many of the remedies for the presumed evils of the system that are proposed by its critics. These remedies frequently show on entire lack of understanding of the fundamental principles of American criminal law, and are proposed with a nonchalance that shows plainly that the writers have no idea that to carry them out would involve a radical change in these principles. For example: The law supposes every man to be innocent until proved guilty, and this supposition continues until a verdict of guilty is actually rendered. The law also puts the burden of proof on the State—the accused must be proved guilty-beyond a reasonable doubt—he does not have to prove himself innocent, but is permitted to use every means to combat the contention of the State. What right then has a judge, for instance, as has been suggested, to say that only Dr. A., Dr. B., and Dr. C. shall testify for the defense, and not Dr. X., Dr. Y., or Dr. Z., when these latter may be reputable alienists, and after a survey of the situation are willing to take the stand for the defense. Would not such action be an arbitrary limitation of the rights of the accused?

This and many other similar principles would, however, never have come into question if it had not been for the attention which prominent trials have directed to the taking of expert testimony. Time and time again in trials involving the question of insanity the public have seen an equal number of equally prominent experts ranged on opposite sides, and have jumped to the conclusion that either the system was bad or the medical expert generally dishonest.

Now let me say right here, from a not very inconsiderable experience, for I have been associated with many trials and heard much expert testimony: I do not believe the expert on insanity to be essentially a corrupt or dishonest person-in fact, I know to the contrary, and consider the criticism that takes this standpoint a base libel on the profession which should be vigorously resented.

This attitude of the public has been largely fostered. I think I may say actually created, by the newspaper reports of trials. Such reports, even in the better class of dailies, are notoriously inaccurate and misleading, while in the type of so called "vellow journals" they not only deviate from the facts, but they are presented in a setting that makes it appeal to the emotions almost to the exclusion of the reason. The former class of papers, while they make a reasonable effort to print things as they really occur, must of necessity depend upon the more or less untrained, immature youth to report them, with the result that the facts are frequently distorted in their passage through this medium to the public. The latter class makes only so much pretense to fact as to avoid, as far as possible, actions for libel, and goes on the principle that they print what the public wants to read. Whatever the explantation the fact remains that the average reports of a murder trial, for example, I know from repeated experiences, give a most inadequate idea as to the real facts of the case and the points of contention, and yet such are the sources which influence opinion, both public and professional.

The reason why experts can be found for either side of a given case is because practically every case that goes into court has two sides, and experts, like other people, are of many minds, and it is naturally no more difficult to get experts who will testify on a given side than it is to get lay witnesses to do so, and yet we never hear a wholesale denunciation of the lay witnesses because they are not all on one side of a case. Each side hunts for an expert who will agree with their theory of the case, and they hunt until they find one. It never appears in evidence how many experts may have refused to testify before the desired one is finally discovered. I know from my own experience, however, that such refusals are far from being the rare exceptions that

some critics would have us believe.

This two sidedness of expert testimony is especially in evidence in will contests. In these cases the individual whose sanity is in question is dead, and the expert is called upon to answer a hypothetical question based upon the testimony usually of untrained lay witnesses. The isolated statements of these witnesses with reference to the savings and actions of the deceased form the basis of this ques-It is hardly too much to say that the isolated sayings and doings of any man, living or dead, taken out of their proper setting, might be put together to make for a diagnosis of either sanity or insanity, and that this is the case in will contests is no fault of the expert or of the lawyer either. Such material is naturally the only material to be had, and as a result a conclusion is difficult to reach. Under such circumstances it would be far more remarkable if men did not differ than that they do.

The mental capacity of a person long since dead is, of course, one of the most difficult problems the expert has to deal with, but the problem in the ordinary criminal trial is rarely simple, and often quite as hard. It must be remembered that the expert is called upon, as a rule, not to testify to the present mental state of the accused, but to his mental condition at the time of the alleged crime, which is usually several months past at least. It is true that he often has the assistance of being able to reason back from a knowledge of his present condition, but this is usually only true if he be an expert for the defense, as the defendant, acting within his rights, often refuses to be examined by the experts from the district attorney's office. When this is the case the expert has quite as difficult a problem as if the person whose mental condition was being in-

quired into was actually dead.

These are some of the fundamental difficulties in every case. In addition to these we must remember that the expert can never hear the other side of the case until it comes to trial, and perhaps then he may not be in court. If he is a very busy man he is apt not to be. In his consultations with the attorney he naturally hears an ex parte statement of the evidence. This must, of necessity, be, because the lawyer can know only in the most general way what points the opposition are going to bring out. This statement by the attorney has some force in moulding the expert's opinion, for be he ever so free from the ordinary frailties of man, he must be on his guard every instant if he is not to be influenced by a statement made with a vigor born of conviction.

Added to these are the difficulties incident to the evidence itself, both from the accused and the various witnesses. The expert is called upon to weigh with great nicety the evidence of numbers of people, some of whom, the accused in particular, are interested in the outcome of the case. He must try to size up all the individuals and give proper weight to the testimony of persons as to the sayings and actions of the accused, who, far from being trained observers, are often ignorant and unreliable to the last degree.

From all this material and under all these difficulties the expert is asked to decide—what? One of the most difficult problems in one of the most obscure departments of learning—the state of a given person's mind at a given time. Surely man is rarely called upon to answer a more difficult question. Can any one who will take pains to look into the situation wonder that the experts are not all of the same mind? Do lawyers and judges, for example, agree any better? Look at the number of decisions that are reversed on appeal, and when we get to that final arbiter of legal dispute, the Supreme Court of the United States, how many of its decisions are unanimous? It is a strange conceit on the part of certain members of the bar who criticise us for not all agreeing—or, as they put it, for being partisan.

The whole principle of the present day trial in court is the principle of conflict. The trial is literally a battle, the two sides being ranged against each other in battle array. Each side musters its forces, and the battle is to the stronger. This perhaps is not the conception that would please the idealist, but is it not as a matter of fact correct? And, after all, has it not the same sanction as the "struggle for existence" and the "survival of the fit" elsewhere?

The expert is accused of taking sides. How can he help it? Could a soldier sent to the front—on the firing line—remain neutral? He might fire into the air, but would he? The expert is in a similar position. From the moment the cross examination commences he is put on the defensive. He may perhaps fire in the air, but if he has the qualities of most men I am much mistaken if we do not find him fighting back before he leaves the stand.

Perhaps all these things are not as they should be, but they flow naturally as the results of the present system of criminal procedure and the makeup of human nature. For neither one is the expert responsible, either directy or indirectly, so why should the blame be all heaped upon him? I confess that I am at a loss for an adequate explanation except that it is a sort of "follow the leader" method of proceeding, it being easier to keep on abusing the doctor than it is to look around for some other cause for the imperfection.

Then there is that other bugbear, the legal test of insanity. This comes of the attempt on the part of the law to define insanity. A rather presumptous undertaking. The physician has taken the ground long since that a definition of insanity is impossible to frame, and about the only excuse ever offered for one is that it may be asked for on the witness stand.

The usual legal test is that the defendant should have known the nature and quality of the act and that it was wrong. The expert is thus put in the position of testifying as to the sanity or insanity of the defendant upon the basis of a test which can have practically no bearing on the question, especially as there is no effort made to define the word know, which, as used in this test, is the crux of the whole situation. The witness is in much the same position when asked to apply this test as if he were shown a red object and asked whether it were green or blue. By the law of error a given number of persons asked such a question would arrange themselves in equal numbers on the sides of the two

Here again the trouble is not with the expert, but with the methods of procedure of which he is forced to be a part and over which he has no control. Criticism of the expert, especially by the lawyer and judge, which has quite recently been indulged in, is practically inept and might well call for comment along the lines of the Biblical query of the mote and the beam.

The real absurdity of the knowledge test of insanity as applied in the courts can be well illustrated by such a case as this: Suppose a man laboring under the delusion that he is being poisoned. He has finally concluded that the efforts at poisoning can be traced to a certain individual. the influence of this belief he plans the assassination of this person, carrying out the crime with deliberation, waiting for his victim at some un-frequented spot, and striking him down at an opportune moment. Now let us suppose for the sake of argument that this man knew full well what he was doing (a supposition that might well be controverted, however), that he knew the act was wrong, and that it was prohibited by law. The essential and to me all important fact remains: the act was the direct product of a disorder of his mind. If he had not been insane he never would have been called upon to deal with his desire to avenge himself, so, whether he could or could not have resisted the act, the crime was committed as the direct result of his illness, and he should be dealt with solely from that standpoint.

The "right and wrong" test, or the test of knowledge as I have called it, like all other legal tests of insanity, should be erased from the statutes. Nothing is to be gained by an endeavor to create a better test—the day of reckoning will only by just so far be postponed. The fetich of the law, precedent, has already continued the present test far beyond the period of its usefulness. Years have gone by, the test has remained the same, but psychiatry has not meantime stood still. There has thus arisen that incubus of practice-the distinction between legal insanity and medical insanity. The "right and wrong test" has prevented the law long enough from adapting itself to the advances in the science of the mind. The only possible way to be always able to adapt itself is, not by creating new tests, which in turn will go through the same history of uselessness as the present one, but by abolishing tests altogether, leaving the way always open for a free acceptance of the results of progress.

The whole scheme, to my mind, of having a jury pass upon a highly technical matter such as insanity is somewhat ridiculous. The jury can at best only make up its mind as a result of the general impression created by the alienists, while the court itself is only too often not only entirely ignorant of the subject, but quite inexperienced.

The court, too, is not infrequently responsible for some of the discredit that has fallen upon expert testimony by the practice of permitting to testify practically any one presented as an expert by either side. The principle enunciated has been that the jury, being acquainted with the witness's qualifications, could take the evidence for what it was worth. I have recently heard a physician testify under this ruling, who, in a practice of some years, had treated only three insane persons.

The trouble is the jury, even after being acquainted with the qualifications of the witness, are not

themselves qualified either by education or experience to judge of his merits. Medical questions are best dealt with by medical men, and it would seem that questions of insanity should be finally passed on by physicians without having their opinions subject to review by juries.

The fundamental defect of the criminal law is that it so often deals with the crime and not with the criminal. For example: A boy snatches a pocketbook without knowing what its contents are. If the book contained less than thirty-five dollars he could only be imprisoned for a period not to exceed one year, while if it contained more than thirty-five dollars he might be imprisoned for as much as ten years, but not less than one year. This despite the fact that in the first instance the thief might be an old offender, a seasoned criminal, a chronic menace to the peace of the community, while in the latter case the offense might be the first committed by a person readily amenable to reform. In any case, the character of the crme as thus set forth in this example is purely arbitrary, and the thief could only be considered constructively to have intended it.

The effort to arbitrarily distinguish crimes as petit larceny and grand larceny, as in example given above, for instance, will always lead to an arbitrary, and to a no inconsiderable degree, unjust administration of justice. Whether a particular individual ever comes within the purview of the criminal law is largely a matter of accident and depends to no small extent upon the ingenuity of the offender. Now, while the object of the criminal law is, or should be, the protection of society, the important question to be solved is not whether the offender stole thirty-four or thirty-six dollars, and is therefore to be indicted for petit or grand larceny respectively, but, What manner of man is he?

In order to answer this question it is necessary to make an analysis of the individual, and the causes leading up to his offense. Only after this is done can a reasonable conclusion be reached as to whether the offender is best treated as a menace to society and put in prison, whether he is a proper subject for reformatory efforts, or whether he might better be paroled with a suspended sentence.

We, as physicians, do not always prescribe the same drug in the same dose for a given disease, no matter in whom it may occur, vigorous youth or decrepit old man. We treat the patient, not the disease, and so in criminology we will never make any further progress under the system of dealing with the crime in the abstract, we must learn to treat the criminal.

In order to divorce criminal procedure from the practice of dealing with the crime instead of the criminal, the assistance of experts in mental disorders and in criminology must be sought, and I believe it is the duty of the State to furnish this assistance, so that it may discharge its responsibilities both to society and the criminal intelligently. This assistance can hardly be expected from the jury or from the overworked court; it must come from a special body of men whose business it is to furnish it.

These preliminary considerations lead logically and. I think inevitably, to the conclusion that the function of the jury should end with establishing the

fact that an offense has been committed by the accused. This fact being established should give the State authority over the person of the offender, and he should be taken into custody, dealt with according to the sort of person he is, and not turned back into the community until he may be with safety, and such action should be as little as possible dependent upon the degree of crime as now defined.

Given then an individual, the jury determines that he has in fact committed an antisocial act. He is then remanded to a court or committee or whatever else it may be advisable to call it, who make a full report to the trial judge upon the character of the offender with recommendations for treatment, such recommendations, so that the amenities may be preserved, to be advisory and not controlling. On the basis of this report the judge pronounces sentence.

Reduced to its simplest terms the whole situation is just this: An individual commits an antisocial act. By so doing the State assumes control of his person and liberty. It does this primarily because it has a right to protect itself from his depredations. Having done so and protected itself, however, it has a further duty both to the individual and to the community. It must endeavor to restore the offender to useful citizenship if that is possible. In other words, it must prescribe a form of treatment suitable to his ailment. In order to do this his case must be diagnosticated. All this is clearly the duty of the State.

Society has too long dealt with crime, either from the standpoint of revenge—the principle of "an eye for an eye, a tooth for a tooth," is the principle upon which our criminal code is built and which controls much of its application even to-day—or from the standpoint of a disagreeable affair with which the easiest way is the best, and so it locks up the culprit, turns its back upon him, and tries to forget all about it.

The time has passed for either one of these attitudes. Revenge may be sweet, but it is usually a pretty expensive indulgence. Crime is a social phenomenon and demands attention if for no other than economic reasons. It is distinctly an unwise policy that continues a system which actually makes criminals. What else can be expected when a young boy for his first offense is ruthlessly shut up in prison to associate exclusively for months with a collection of the worst and most incorrigible offenders? It is a distinct duty, pointed to by actual dollars and cents economy, to keep men out of prison, or if they get in to restore them to independence at the earliest possible date. These results will never take place until we learn to deal with the criminal and not the crime.

This would seem to be the rational method for the State to pursue. How can it best be accomplished? If insanity is the defense the defendant should be sent to the nearest State hospital for the insane. Surely if a person is insane the place for him is in an institution for the insane and not in a jail. Not only this, but only under the close observation possible in a hospital can the best results as to the diagnosis of the condition be expected.

This method of procedure I believe would be a good one, even if the conclusions of the State hospital authorities were not considered final, but mere-

ly introduced in evidence to be combated like other evidence. Under such circumstances they would easily have a preponderating influence as coming from an entirely unbiased quarter, as has recently been well illustrated in St. Louis.

This sending of the patient to a State hospital for a report on his condition may be delayed until the jury has returned a verdict if thought best to preserve the rights of the accused. Sentence will be passed, or from our viewpoint, a line of treatment prescribed, only after a diagnosis has been reached.

In order that the State hospitals may be able to meet this class of problems, I believe each one should have specially constructed quarters, or, better, a special group for the observation, care, and treatment of this class of cases. A special detached group would probably be warranted in all the larger State hospitals, for in this group would naturally be cared for, in addition to the "court cases," the several vicious characters of the insane population, of which each institution always has a number.

This grouping of the noncriminal with the criminal insane may be objected to by some. It is, however, an entirely reasonable procedure when it is considered that we are dealing with the individual in each instance and not the isolated result of some one of his acts. Whether a given person comes within the purview of the criminal law or not is often purely a matter of accident. The point to be considered solely is the character of the person he is, and if he has manifest criminal and vicious tendencies he should be separated from the general population of the hospital and treated and cared for with his like.

These are lines along which, in my opinion, we may look for betterment of present conditions. There are already plenty of well recognized principles of criminology which have yet to be adopted in many communities. A parole system and the indeterminate sentence are among the most important. While such defects exist, the way to the correction of which is so clear, it would be far better if all would put their shoulder to the task of trying to accomplish something of the sort rather than indulging in wholesale denunciations. The man of action cannot stop on the road of progress and argue to its bitter end every difference of opinion. There are things to be done. Let us do them.

With the subject of this paper in mind there is one thing that President Roosevelt has done which is most pregnant with possibilities. I refer to his organization of the House of Governors. are many questions which are not affected by State boundaries. Murder is the same on the Pacific coast as it is in the Gulf States, and should be dealt with in the same way. There should be no reason why enlightened legislation which has been found of advantage in one State should not be adopted by all, and the House of Governors forms an ideal clearing house and administrative system for securing these benefits. Let us hope to see the governors of the several States meeting together each year, like our National Medical Socities do, and discussing such problems as the revision and unification of the criminal code. France remodeled its code Napoleon. Germany had its experts at work for years on its criminal code. Surely we should begin to

think of approaching the problem in a broad and comprehensive way. The Federal Government has created a Statutory Revision Committee; let us hope it will point the way in its recommendations regarding the criminal law.

INTRAPELVIC VERSUS ABDOMINAL METHOD
OF DEALING WITH MECHANICAL OBSTRUCTION TO DELIVERY IN
CASES OF CONFINEMENT.

By Egbert H. Grandin, M. D., New York,

Consulting Gynæcologist to the French Hospital; Attending Gynæcologist to the Columbus Hospital; Associate Surgeon to the Woman's Hospital in the State of New York.

Mechanical obstruction to delivery may be offered: 1, By the pelvis; 2, by tumors in the lower uterine segment or of the vagina; 3, by the presenting fœtal part; and 4, by the cervix of the uterus.

I take it that for the purpose of this discussion, description of operative technique is uncalled for, and that we are viewing the woman only at the stage when induced labor with viable child still

enters as a factor.

1. Mechanical Obstruction due to the Pelvis .- I shall eliminate from this discussion at once instances of absolute pelvic contraction. Here, from the very nature of the problem, the suprapubic method alone enters into the question unless embryotomy be elected. In lesser degrees of contraction, of no matter which type, induced labor should be the operation of election. The rule I have laid down for myself is a simple one: Just as long as under suprapubic pressure the presenting part can be made to accommodate itself to the pelvic brim, just so long may we refrain from interference. When accommodation begins to fail, then, after one or another fashion, labor should be induced, irrespective of the fact that prematurity of the child is against its survival. This rule is for me an absolute one, unless the parents elect a major operation at term. Where the case is not seen until the time for the rational induction of premature labor has passed, that is to say, the presenting part cannot be made to enter the pelvic brim, the choice lies between forceps, version, and the abdominal Cæsarean section. There are here a number of factors which control our choice of method. Ideally the Cæsarean section, before the onset of labor or just after, should be elected. Such election, however, in private practice, is alone possible where the consent of the man and the woman is secured. The glamour surrounding the statistical data offered by individual operators should not blind us to the fact that all women cannot control the services of the expert. My rule is, if the Cæsarean section is declined, to calmly await the advent of labor, and, when the proper conditions are present, to perform an elective version. My experience has taught me that when, under the natural efforts, the presenting head does not engage, it is safer for the maternal parts and less dangerous to feetal life to deliver by the more readily moldable after coming head than to drag the before coming head through by forceps.

And this leads me to state, in brief, my views in reference to this instrument. High forceps, that is to say, where the fœtal head is not engaged, I look upon as one of the major obstetric operations. I say this even though, with the aid of the only type of forceps I admit under this condition—the axistraction-I have been enabled, by means of careful and protracted intermittent traction, to deliver without extreme injury to the maternal parts. Where the head has engaged by its greater segment, a condition which I am not considering now, we cannot longer speak of as high forceps. This is median forceps, an entirely different proposition. The version having been accomplished, where delivery fails. if the fœtus is still alive and consent of the parents is secured, I find a field for symphysiotomy, since the alternative is embryotomy. Even so, basiotripsy of the after coming head carries less risk of injury to the woman than perforation of the before coming head unengaged at the brim. Hebosteotomy, in view of the lesions suffered by the woman-and all who have read recent American literature will agree with me that they are little short of damnable-I unhesitatingly reject. Where the presenting part of the fœtus is other than the head, considerations offer which will best be noted under the subdivision relating to the fœtus. Under the present subdivision neither the Dührssen operation nor the vaginal Cæsarean section claim consideration.

2. Mechanical Obstruction Due to Tumors in the Lower Uterine Segment or Occluding the Vagina. -This phase I shall not dwell upon in extenso, since the time limit imposed on the discussion does not permit. Broadly, it holds that tumors of the vagina and tumors of the cervix and impacted degenerated growths should be removed by the vagina and then the condition of the pregnant uterus and its contents should be met according to the indication. Tumors of the lower uterine segment admit of but one course, and this the abdominal route, and hysterectomy or enucleation with Cæsarean section according to indication. Pelvic tumors, solid or fluid, not degenerated, call for abdominal section, removal, and the Cæsarean section. These general rules will not suffer modification, whether the pelvis or the fœtus offer abnormality or not. The rules applicable to such abnormalities, irrespective of the

presence of tumor, are to be enforced.

3. Mechanical Obstruction Due to the Fætus .-Here we face the problem which carries greatest difficulty in solution, for the simple reason that where the presentation is normal we are not in a position of estimating with accuracy the size of the head, and, further still, in fat women, the position. Very commonly careful pelvic mensuration and internal manual examination simply lull us to sleep, for at labor we find that, although the pelvis is normal, the presenting part is the reverse. I have stated before my preference for version and my objections to high forceps, and as regards the latter, I wish to further say that, whenever, under the influence of well directed uterine efforts, the head does not engage. I am opposed to tentative forceps traction. They teach us nothing more than Nature has already taught us. Where the conditions for version are failing-that is to say, head above the brim or slightly engaged and movable and mem-

The serve of the Grant of the Political Research

branes unruptured-in preference to forced version I would advise symphysiotomy. Let me repeat that here again I repudiate hebosteotomy. In the event of the pelvis being abnormal, with complicating excess in size of the fœtal head, when satisfied that the mechanical problem is such that this head cannot enter the brim, the consent of husband and wife should be secured and an abdominal Cæsarean section performed, the child, of course, being viable and alive, and the physical condition of the woman not contraindicating. In these instances, obviously, neither the Dührssen operation nor the vaginal Cæsarean section enter as factors. Where the presentation is other than the head, and the dystocia is simply due to the malpresentation, the ordinary rules of obstetric procedure apply. Where, in addition to the malpresentation, there exists pelvic contraction, our choice of method for delivery should be again the abdominal Cæsarean section, other things being equal.

Under this heading, as under the previous, I have refrained from dwelling upon types of deformity, and entering into consideration of pelvis measurements, since the time limit only permits of the

expression of general deductions.

4. Mechanical Obstruction Depending upon the Cervix.—Here we approach a phase where opinions are greatly divided and where such differences are to be expected. The conditions calling for interference and at times demanding rapid delivery are the toxemias, and, broadly speaking, the hemorrhages. It is not so much a question of fœtus and woman as it oftentimes is of woman alone. Primarily neither forceps nor version enter into the question, nor, as I shall contend, is it a question of the abdominal Cæsarean section, except we are also facing a decided grade of pelvic contraction, the time suitable for the induction of premature labor for the sake of the child having passed. We have reached the phase of the proposition where the Dührssen operation and the vaginal Cæsarean section enter the field.

First, as regards the toxæmias. Under this generic term I include the morbid phenomena emanating from kidney, liver, intestinal canal, and, hypothetically, the fœtus. The type of operation selected will not depend so much on the variety of toxæmia uppermost as on the degree and the imminence of fatal symptoms. I take it that we are all fairly well in accord that, when the time for surgery comes, the kind demanded is that which will enable us to empty the uterus of fœtus within as short a time as is possible, paying due regard to the integrity of the maternal parts. I take it also that we are all agreed that the tendency of the average man is to wait too long before resorting to interference. These premises being granted, let us look at this topic from the standpoints of impending risk to the woman, and sudden, present risk. Where clinical tests teach us that the toxæmia is deepening, as a rule there is sufficient time limit to enable us to dispense with either the Dührssen operation or the vaginal Cæsarean section. Here the mechanically obstructing cervix requires simply the attention I have been harping upon most of my professional life-gauze packing to cause it to soften and to

merge into the lower uterine segment, followed by manual dilatation and delivery. At any time after merging of the cervix, where greater rapidity of operating is demanded than the hand yields, the Dührssen operation finds its legitimate field.

Where, on the contrary, the toxic symptoms are of high grade, then the vaginal Cæsarean section enters most beneficently. I cannot conceive, in the absence of pelvic contraction sufficient to rule out these pelvic procedures, of the abdominal Cæsarean section ever being justifiable in face of the toxæmias.

Next as regards the hæmorrhages complicated by dystocia due to the cervix. Concealed hæmorrhage, as soon as diagnosis is reached, calls for immediate emptying of the uterus. Here, then, when the vaginal portion of the cervix has disappeared, the Dührssen operation offers, otherwise a rapid vaginal Cæsarean section. Slower methods will not answer, since the woman's life is at stake.

The hæmorrhage of placenta prævia may be viewed more philosophically. Where high grade pelvic contraction does not complicate, I cannot grant that the abdominal Cæsarean section is ever allowable. When the time element permits I still plead for gauze packing, to secure softening and merging of the cervix, followed by manual dilatation and delivery. Rarely, very rarely, in my experience, will the case offer such urgency as to demand other procedure. The vaginal portion of the cervix having disappeared, a rigid lower segment may demand the Dührssen incisions. As regards the vaginal Cæsarean section, I can simply state that I have never seen a case of placenta prævia where it was indicated. In any event I should look upon this as a very desperate procedure except in case of marginal insertion, and here the hæmorrhage is never so profuse or the life of the subject in such danger as to demand it. It should be borne in mind that in case of central insertion, profuse hæmorrhage carries well nigh absolute fatality for the fœtus, and that, therefore, the interests of the woman need alone, as a rule, be taken into account.

It will be noted that I reject, for the present, hebosteotomy as an alternate operation. I would state that my position is based on the American statistics, since I much prefer to judge an operation from home data, knowing the calibre of home operators. From this standpoint, I cannot concede that the statistics are as favorable as those offered for symphysiotomy by men of similar calibre. Taking expert American operators, the later operation never yielded the untoward sequelæ which, up to date, the former has. 'For proof of this assertion I need only refer you to the paper presented to this society at its meeting in 1907 by Henry D. Fry. Neither of these operations can become elective, and when a narow outlet is the cause of the dystocia, the child being alive, judged by their fruits, symphysectomy must be preferred to hebosteotomy

Such briefly are the opinions which I hold for the purpose of this discussion. Some are elementary and well established, others are open to criticism by those with different, probably equally well founded experience. There are certain general deductions I wish specifically to establish: First, I am in hearty accord with the modern tendency of

widening the sphere of the elective Cæsarean section; second, I do not believe that either symphysiotomy or hebosteotomy can ever be made operations of election, and that, when either is demanded, the first should be given the preference; third, as I view an experience of nearly thirty years, I am glad Nature may now rarely cause me to destroy the living child.

116 WEST SEVENTY-SIXTH STREET.

DIES CANICULARES.

"Dog Days": "The Physitians Vacation." By John Knott, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc., Dublin, Ireland.

(Continued from page 155.)

The yearly recurrence of the tidal flow and ebb of the waters of the silent and mysterious Nile was one of the most interesting, physically, as it assuredly was the most important, economically, known to the cultivators of the land from which Greece and Rome originally derived the principal items of their germinal mythology. And of the explanations of its occurrence which had been collected or invented by the more noted Grecian sages, Plutarch has tabulated a series which will, I believe, be found to contain almost all the items reproduced since his time-even down to the date of the publication of the blue jacketed volumes inspired by the construction of the Assouan dam:

Thales thinketh that the anniversary winds called Etesiæ blowing directly against Egypt, cause the water of Nilus to swell; for that the sea being driven by these winds, entreth within the mouth of the said river, and hindereth it, that it cannot discharge it selfe freely into the

sea, but is repulsed backward.

Euthymenes of Marseils, supposeth that this river is filled with the water of the Ocean, and the great sea lying without the continent, which he imagineth to be fresh and

Anaxagoras saith that this hapneth by the snow in Æthiopia, which melteth in summer, and is congealed and

frozen in winter.

Democritus is of opinion, that it is long of the snow in the north parts, which about the Æstival Solstice and return of the Sun, being dissolved and dilated breedeth vapors, and of them be engendred clouds, which being driven by the Etesian winds into Æthiopia and Egypt toward the south, cause great and violent rains, wherewith both lakes, and the river also Nilus be filled.

Herodotus the Historian writeth, that this river hath as much water from his sources and springs, in winter as in summer; but to us it seemeth lesse in winter, because the Sun being then neer unto Egypt, causeth the said water to

evaporate

Euphorus the Historiographer reporteth, that all Egypt doth resolve and run as it were wholly into sweat in sum-mer time: whereunto Arabia and Libya do confer, and contribute also their waters, for that the earth there is light

and sandy.

Eudoxus saith that the Priests of Egypt assign the cause hereof to the great rains and the Antiperistasis, or contrary accurse of seasons; for that when it is summer with us, who inhabit within the Zone toward the Summer Tropick, it is Winter with those who dwell in the opposite Zone under the Winter Tropick, whereupon (saith he) proceedeth this great inundation of waters, breaking door, until the trace Volta

The river below and the star above were almost correspondingly inspiring and productive-in the genesis of philosophic opinion, and stimulation to speculative research. The solstitial approach of

Sirius in the mouth of the watch dog vied in the dignity and importance of the significance of its ascent with the midnight appearance of Vindemiatrix in the left elbow of the headless virgin, on the horizon at the winter "sunstead" of six months later. One announced the coming recreation of the country's soil and vegetation by the swell of the heaven sent stream of the Nile; the other heralded the rebirth and resurection, from the dark abysm of the nether (or other) world, of sol invictus himself, the creator and preserver of all forms of life. And well was it said by the "wisest [and by no means the "meanest"] of mankind" that a little learning disposeth a man to atheism, but a continued penetration into the depths of the same tends to bring him back to the preserving sheepfold of religious belief. The scoffing "modern" materialist, superficially educated as he nearly always is, would act well towards himself, as well as benevolently to all his possible hearers and readers, in suppressing the disposition to formulate his personal inspiration of the syllabus followed out by the supreme power in the construction of the universe and the gradual revelation of its mysteries to man. If he persists in his inquiring research he will find pretty surely that all his best thoughts have been long ago expressed by others, and that all the queries and doubts of the philosophers of all the countries were thoroughly tested and assimilated or rejected, according to their respective merits, by the founders and builders of the Christian Church.

In the seventeenth century, that era of boasted scientific illumination and progressive intellectual emancipation, there appeared from the pen of Petrus Servius ("Spoletinus, in Gymnasio Rom. Medicinæ Theor. Ord. Professoris P.") a booklet bearing the superscription: Dissertatio de Unguento Armario et Sympathico vulgo Apellato; sive de Naturæ Artisque Miraculis. And one of the included problems of nature miracula, to be there found tabulated by the critical author, is thus enunciated:

Quid mirabilius Nyli terra, quæ exiccata illa quidem ac diligenter asservata, eodem semper pondere gravis est; ad xvii vero diem Junii nullius rei accessione, se ipsa pon-

The irresistible affinity of the Nile mud for moisture, which thus developed at the approach of the æstival solstice, would almost seem sufficient, in the mind of this querist, to account for the seasonal swell of the stream from that of the bank or bed of which it was derived!

We may probably regard the pages of Caius Plinius Secundus as the most faithful reflection of the curiously chaotic condition of physical knowledge in his time; with its hopeless entanglement of natural history and divinity, of meteorology and metaphysics, of mythology and mendacity and credulity. And there we find this account of the annual inundation of the Egyptian "father of waters":

Many and divers causes of this rising and increase of his, men haue giuen; but those which carry the most probabilitie, are either the rebounding of the water, driven back by the winds Etesiæ, at that time blowing against it, and driving the sea withal vpon the mouths of Nilus; or else the Summer rain in Æthiopia by reason that the same Etesiæ bring clouds thither from other parts of the world. *Timeus* the Mathematician, alledged an hidden reason thereof, to wit, that the head and source of Nilus is named Phyala, and the river it selfe is hidden, as it were drowned within certain secret trenches within the ground, breathing forth vapors out of reeking rocks, where it thus lieth in secret. But so some as the sume during those daies, commeth neere, drawne vp it is by force of heate, and so all the while he hangeth aloft, ouerfloweth; and then againe for feare he should be wholly deuoured and consumed, putteth in his head againe, and lieth hid. And this happeneth from the rising of the dog starre Sicinus, in the Sunnes entrance into Leo, while the planet standeth plumbe ouer the fountaine aforesaid: for as much as in that climate there are no shadows to be seene. Many againe were of a different opinion, that a riuer floweth more abundantly, when the Sunne is departed toward the North pole, which happeneth in Cancer and Leo: and therefore at that time is not so easily dried: but when he is returned once againe back toward Capricorn and the South Pole, it is drunke vp, and therefore floweth more sparely. But if according to Timeus a man would thinke it possible that the water should be drawne vp, the want of shadowes during those daies, and in those quarters, continueth still without end. For the riuer begins to rise and swell at the next change of the Moone after the Sun-steed, by little and little gently, so long as he passeth through the signe Cancer, but most abundantly when he is in Leo. And when he is entred Virgo, he falleth and settleth low againe, in the same measure as he rose before. And is cleane brought within his bankes in Libra, which is, as Herodotus thinketh, by the hundreth day.

The periodic wobble of the terrestrial axis, which accounts for the genesis of the cosmic phenomenon of the precession of the equinoxes, accounts, of course, for the continuous change of the zodiacal relationship of the onset of the annual inundation of the Nile. But there is no doubt that in the twilight period of the early astronomy which has been definitely reflected down to our twentieth century vision the heraldic sign of the Nile flow was Leo. The primogenital importance and significance of the symbolic standard of the tribe of Judah must have been early impressed on the Hebrew lawgiver-even long before the vision of the burning bush. And Gentile poets found plenary inspiration in the linking of phenomena associated with the relationship of Sol and Leo in the heavens above with Nilus and its waters on the earth beneath. Thus Aratus:

> Πελίου τα πρώτα συνευχομένου λέοντι Τέμος και κελάθοντες έτησίαι εύρει πόντφ Άθρου έμπίπτουσι.

-making the dog star, the etesian winds, and the Nile tide all to appear with the entrance of the sun into Leo. And the hieroglyphic and philosophic hierarchy, whose nation depended for existence on this annual inundation, made their terrestrial fountains to spout from symbolic lions' mouths-thus continuously presenting a terrestrial memento of the celestial source of that most precious gift or heaven to earth. How blissfully unconscious is the "cabby" of our own St. Stephen's Green, as he waters his thirsty steed at the memorial fountain which decorates its northern margin, or the parched street Arab who refreshes himself from one of its chained up chalices, of what an enormous mass of fable and fact has in the course of the world's history collected, or been deposited, around the nucleus originally furnished by the apparently meaningless lion's head, from the open mouth of which gushes the stream of refreshing liquid!

So inseparably associated were Sirius and Nilus in their respective annual ascents, that the very aspect of the star on the occasion of its first appearance distinctly foreshadowed the degree of the swell of the fertilizing stream, and the consequent pro-

portion of plenty and prosperity which might be expected in the land of Egypt during the ensuing year. As the very learned Salmasius puts it: "Inde et veteres Ægyptii considerabant ortum sirii, ut ex ejus figura conjectarent, an bene sperandum esset de ascensu Nili, qui utique subsequebatur." The unique interest and importance of the yearly Nile tide figured so prominently in the atmosphere of philosophic thought, that Lucretius could not consider his metrical exposition of the Epicurean philosophy complete without discussing the unique phenomenon, in his closing book:

Nilus in æstatem crescit, campisque redundat, Unicus in terris Ægypti totius amnis: Is rigat Ægyptum medium per sæpe calorem;

Flumine, quæ gelidis ab stellis axis aguntur:

And as the soil of Egypt was actually the yearly donation, we can hardly wonder at the Egyptian idea that our planet came into existence with the rising of the dog star: "Ideo et natalum mundi Ægyptii sacerdotes eo die constituisse videntur, quo Sirius oriebatur, quia ut plurimum tunc Nilus crescere incipiebat, cujus àvastacent felicitas illius terræ constabat." And the twentieth century reader may be reminded, as he glances with amused contempt at those childish conceptions of a remote people in a remote age, that the physical portion at least of the chain of reasoning which led to the selection of that Egyptian date of the creation may bear favorable comparison with Lightfoot's famous demonstration from the Biblical text that "heaven and earth, centre and circumference, were created together, in the same instant, and clouds full of water"; and his chronological proof that "this work took place and man was created by the Trinity on the twenty-third of October, 4004 B. C., at nine o'clock in the morning." [The profound attainments of Dr. John Lightfoot (1602-1675) in rabbinical lore and in the languages of the Divine books were universally recognized in his generation, and the great English University of Cambridge was proud to choose him for its Vice-Chancellor.] After noticing this interesting item in the advancement of human knowledge in general, and of cosmic chronology in particular, we may probably incline to regard from a more liberally critical standpoint, the Egyptian date of the starting of the mundane machine on its perennial race, as mentioned by the same Salmasius:

"Inter tertium decimum et undecimum vult natalem mundi fuisse juxta Ægyptiorum sententiam,

hoc est, duodecimo kalendas Augusti."

As a well defined quadrantal division of the annual cosmic orbit was distinctly indicated by the

nual cosmic orbit was distinctly indicated by the four cardinal points of the yearly cycle—two solstitial and two equinoctial—the chronological cosmogonist pretty surely took his original starting post at a position closely related to one of these. And as the choice of one doctrinaire has evermore excited the diametric opposition of another, and the shunting side thrust of a third cogitator who wished to catch the collective mental eye of the same audience, the inevitable result has been that an intellectual fortress has been raised in the vicinity of each of these four temporal landmarks, for the avowed purpose of defending its unique claim to primary position in relation to cosmic time. Egyptian

thought and attainment germinated on the soil of Greece. Imperial Rome conquered and altered.

Αιγοπτίους δε άργη έτους σύχ υδραχόσο ώς Ρωμαιους, άκλα χάρχινος. Πρός γαρ τοῦ χαρίνου η σούθες ην χονός άστερα ο "Εκκηνές φάσι. Νουμήνια δε όντοις η σούθεως άνατοκη γενέσεως χατάρχουσα της εις τον χάσμον.

At that remote point in the orbit of the equinoxial procession at which the foundations of early Egyptian cosmogony and theology were so firmly laid, the dog star manifested a solstitial relationship—in concert with the zodiacal sign of cancer, and the recreation of that part of the earth's surface by the spreading flow of the annual Nile tide. The Roman theologian from an environment of inspiration so widely different, placed his first day of terrestrial time directly after the date of the annual rebirth and resurrection on high of the triumphant sol invictus, whose creative and regenerative powers were indisputable, and whose three days' sojourn in the darkness of Adyr he had just before been mourning. Then we find the Venerable Bede in the eighth century, and Vincent of Beauvais in the thirteenth, enunciating (and proving) the fact that the world must have been created in spring. And so around the Solar cycle!

The multitudinous testimonies to the fructifying, and even creative, power of the waters of the Nile receive further curious corroboration from the ever encyclopædic Pliny, in his chapter of Prodigious and Monstrous Births:

That women may bring forth three at one birth appeares euidently by the example of the three twins Horatii and Curiatii. But to go aboue that number is reputed and commonly spoken to be monstrous, and to portend some mishap: but only in Egypt, where women are more than ordinary fruitfull, by drinking of Nilus water, which is supposed to help generation. Of late yeres, and no longer since than in the later end of the reigne of Aug. Casar, at Ostia there was a woman (a Commoners wife) deliuered at one birth of two boies & as many girles, but this was a most prodigious token, and portended no doubt the famine that ensued soone after. In Peloponnesus there is found one woman that brought forth at foure births 20 Children, and the greater part of them all did well and liued. Trogus saith, that in Egypt it is an ordinarie thing for a woman to have seuen at a birth. It falleth out moreuer, that there come into the world children of both sexes, whom we call Hermophrodites. In old time they were knowne by the name of Androgyni, and reputed then for prodigious wonders, how socuer now men take delight and pleasure in them.

And thus were the supernatural powers of the "heavenly gift" of the Nile stream made manifest on earth among the human dwellers on its banks, by its genial promotion of their reproductive capabilities!

The brilliant monarch of the fixed stars had, as an obvious necessity of its associations—with light, with heat, and with moisture—a triplex influence on all important matters mundane. The brilliancy of its light was, unquestionably, unrivalled in the starry firmament; its solstitial connection gave it a fixed attachment to elementary heat; while its uniquely peculiar association with the annual tide of the Egyptian "father of waters" was conclusively demonstrative of its relationship to the fructifying element of moisture. With such physical (as well as celestial) associations, it must necessarily be endowed with a very large proportion of directive power in the general management of the physical

condition of the human body—and also of the control of the efficacy of remedies thereunto applied in the practice of the healing art. Every influence which was situated on the circumference of a cosmic sphere necessarily exerted a certain proportion of the same on the central microsmic unit, man; and such celestial influences upon objects terrestrial were added or subtracted according to conjunction or opposition.

Pythagoras by Musical proportion calleth that a Tone, by how much the Moon is distant from the Earth: from the Moon to Mercury the half of that space, and from Mercury to Venus almost as much: from Venus to the Sun sequiple: from the Sun to Mars a Tone, that is as far as the Moon is from the Earth: from Mars to Jupiter half, and from Jupiter to Saturn half, and thence to the Zodiack sesquible: thus there are made seven Tones, which they call a Diapason harmony, that is an universal concent: In which Saturn moves in the Dorick mood, Jupiter in the Phyrgian, and in the rest the like. Those sounds which the seven Planets, and the Sphere of fixed Stars, and that which is above us, termed by them Antichthon, make, Pythagoras affirmed to be the Nine Muses: but the composition, and symphony, and as it were connexion of them all, whereof as being eternal and unbegotten, each is a part and portion, he named Mnemosyne.

Such is Stanley's version of the paragraphs of Pliny and Porphyry. And so we still have Apollo (sun, sun-god, savior, destroyer, healer, musician) conducting the diurnal concert of the music of the spheres. And to the naked-eve observation of even the uneducated and unknowing still reappears perennially the same vision which is portrayed in the divinely inspired descriptions of the prophecy of Ezekiel and the Apocalypse of the latest of the Evangelists: the four "royal" stars that form the cardinal pillars on which rests the celestial firmament, the symbols of the respective constellations of which (Aquarius, Leo, Taurus, and Aquila) have been so appropriately adopted by Christian theologians and artists, as the heraldic emblems of the several authors of the four Gospels which contain the divine revelation of the new covenant of the ruler of Heaven above with his subjects on the earth beneath.

As the heliacal manifestation of the existence of the dog star above the Egyptian horizon always proved the reliable herald of the approach of the hottest season of the northern hemisphere, as well as of the life preserving periodic inundation of the Nile, the same stellar messenger became unavoidably associated in the popular mind with the highest range of annual cosmic temperature; and hence the application thereunto of the adhesive epithet of "dog days." The logic of the many headed would appear to have been always the same-in every race and nation, and at every period of the world's history. And, in strict conformity with its suggestions in this connection, we have the mediæval record of the formation of Goodwin Sands by the geological influence of Tenterden steeple; of the origin of syphilis from a certain planetary conjunction, of specially malignant influence on human health and vigor, which happened in the year of grace 1483; of the cause and effect relationship of certain memorable eclipses and earthquakes, of comets and political revolutions, of volcanic eruptions and epidemics, of sunspots and cyclones, of microbes and contagious

What was the efficient agent which called canine

rabies and human hydrophobia into existence so much more readily at the period of the presiding influence of the celectial canicula? was a question with which was associated a degree of absorbing interest that produced (or created, or inspired) various attempts at solution even in those remote classical and preclassical centuries which so long preceded the discovery of the sublime truths of bacteriological pathology, and the consequential invention of antirabic serum and the edification of Pasteurian institutions. The generally received fact of the actual association of dog madness with the annual recurrence of dog days has-in the usual course of things -been often contradicted. Ulisse Aldrovandi, whose tercentenary was so joyously and graciously celebrated last year in his own well beloved University of Bologna, collected more natural history lore, on this as on all other available subjects of interest, than did anybody else of whom I have heard or readwith the possible exception of King Solomon him-And that enthusiastic explorer of the secrets of the cosmos admits the greater frequency of canine madness at this season: "Non negamus quidem diebus præsertim canicularibus, canes rabie agitari" —but explained the fact by the nutritional influence of the putrid flesh (and varied filth) and the contaminated water, of which dogs were so much more frequently obliged to partake at this season. He refers to the popular idea, which would seem to have been widely distributed, of the origin of canine madness from the imbibition of the menstrual blood of the human female, but does so in a tone of depreciation; and refers, in its disfavor, to the morbidly instructive report of the observation and experience of Matthiolus, the father of modern therapeutics: "Cum ipse noverit mulieres, quæ non alia de causa catellos Meliteos domi alebant, quam vt dum mensibus laborarent, ea excrementa lingerent, quæ concreta pudendis partibus inhærebant, quos canes cunnilingos vocant, nec tamen, ob hanc causam, aliquo rabiei periculo agitati sunt." Such was the function of the Roman lady's "lapdog" in the age of the Renaissance; quite reminiscent, indeed, of the moral hygiene and special sexual practices of the corresponding personalities of the days of Martial! And the very copious therapeutic armamentarium of the elder Pliny includes some items and explanatory suggestions in connection with the use thereof, which prove the prevalence of this idea of the ætiology of canine madness in that author's day. In one place he informs the reader that:

Lais and Salpe, two notable strumpets, have left in writing, that if the foresaid menstruous bloud bestowed within a little locke of wooll that came from a blacke Ram, be worne inclosed within a siluer bracelet, it is a soueraigne remedy against the biting of mad dogs, and for Tertian and Quartan agues.

That was, of course, an instance of the almost universal belief in the efficacy of amulets and allied (sympathetic or remedial) preventive and curative agents, which was diffused through the whole atmosphere of the very "natural" theology of the various Gentile nations in the pre-Christian centuries; and which can hardly be said, with an approximation to absolute veracity, to be completely dissipated at the present moment. The same author gives an instance of the quasimiraculous power of sympathetic therapeusis of the same disease, which simultaneously recalls the methods of homeopathy and of

Icetidas, a worthy Physitian among the Greeks, assureth vs vpon his word, that Quartane agues will make an end and go away by the act of generation, at what time onely as a woman beginneth to enter into her fleurs. But this is agreed vpon by all authors professed and seen in this theam. that if one be bitten with a mad dog, and so far gone, that he is afraid of water, so as he dare not see it or drink at all, do but put a clout or shred of cloth dipped in the said menstrual bloud under the cup whereout hee is to drinke, hee shall immediately be deliuered from that feare: And this commeth by that powerfull and predominant Sympathie, whereof the Greeks write so much, between mad dogs and the said bloud, considering as I haue before said, that they begin first to run mad by tasting thereof.

Not only the morbid influence of the much maligned menstrual discharge was credited with the genesis of rabies, but even the carminative powers of certain items of the vegetable kingdom were believed to be productive of corresponding results. The danger of allowing dogs to partake of such aromatic condiments as pepper and ginger is carefully indicated to the reader by the universal Aldrovandus: "Præterea cum omnivorum sit animal cavendum est, ne iuscula piperate, vel zinzibere aliisque aromatibus condita sorbeat, quoniam hæc ob insignem caliditatem canes in rabiem pellere possunt."

The peculiar exuberance of fallacy of equivocation which has for untold centuries been encouraged to vegetate around the canine associations of this star and this season, has been further cultivated by the copious interpretative comment to which the well known aphorism of the Father of Medicine has given rise in connection with the nomenclature and folk lore of the dies caniculares:

Πρά κυνός και ύπο κύνα ερνώθεες αι φαρφακτιαι Ante canis ortum, et torrente cane, molestæ sunt purgationes. (Lefebure di Villebrune's version.)
In and a little before the Dog days, Purgations are

troublesome. (Sprengell's version.)

Such authoritative pronouncement, couched in language so apparently uncompromising, did not rail to stamp a powerful influence on medical practicethroughout the more cultured areas of western Europe for fully two thousand years. The coincidence of two such physical factors as are there indicated, linked by the bond of danger, could not fail to associate the modifying season with the latter-inthe relationship of cause and effect. The logic of the unspeakable multicapitate was of the same flavor as evermore. That the author did not anticipate the development of the received interpretation was clearly pointed out by Galen. This latter famous philosopher and physician definitely expressed the opinion (in the language of the Pseudodoxia Epidemica) that: "If the same compute of times and months were observed by all nations, Hippocrates had never made any mention, either of Arcturus, Pleiades, or the Dog Star." The reference to a peculiarly brilliant and celestial object was due to the fact that it formed so prominent a milestone in the annual cycle of the seasons; and its name being, in this connection, practically synonymous with the astronomical term solstice. This source of a widely diffused "vulgar errour" was dwelt on at some length by the celebrated author of the Religio Medici, whose comment on the dictum of his medical predecessor of some one-and-twenty centuries before may be read with profitable interest even at the present day:

The condition of the disease, and the intention of the Physitian, hold a main consideration in what time and place soever. For Physick is either curative or preventive; Preventive we call that which by purging noxious humors, and the causes of diseases, preventeth sickness in the healthy, or the recourse thereof in the valetudinary; this is of common use in the spring and fall, and we commend not the same at this season. Therapeutick or curative Physick, we term that which restoreth the Patient unto Sanity, and taketh away diseases actually affecting. Now of diseases some are cronical, and of long duration, as quartane Agues, Scurvy, etc., wherein because they admit of delay we defer the cure to more advantageous seasons. Others we term acute—that is, of short duration and danger—as Fevers, Pleurisies, etc. In which, because delay is dangerous, and they arise unto their state before the Dog daies determine, we apply present remedies according unto Indications; respecting rather the acuteness of the disease, and precipitancy of occasion, then the rising and setting of Stars; the effects of the one being disputable, of the other assured and inevitable.

Following up the current of critical thought manifested in these general observations, Sir Thomas Browne proceeds to examine in careful detail the facts and fancied proofs associated with the growth and development of this item of astrological lore, with its supposed influence on the course of matters medical. And in no case, perhapes, does he display more logical skill and reasoned care than in dealing with this "vulgar errour":

which seems to be the ground of this assertion, and not to be drawne into question, that is, the magnified quality of this Starre conceived to cause or intend the heat of this season, whereby these dayes become more observable then the rest, we finde that wiser Antiquity was not of this opinion, which seven hundred yeares agoe was as a vulgar error rejected by Geminus, a learned Mathematician in his Elements of Astronomy; wherein he plainly affirmeth, that common opinion made that a cause, which was at first observed but as a sign. The rising & setting both of this Star & others being observed by the Ancients, to denote & testific certain points of mutation, rather then denote at testine certain points of industors, rather dis-conceived to induce or effect the same; For our fore-fathers, saith he, observing the course of the Sun, and marking certaine mutations to happen in his progresse through particular parts of the Zodiack, they registred and set them downe in their Parapegmes, that is, certaine Astronomicall Canons, as Rhodiginus out of Vitruvius interprets it; and being not able to designe these times by dayes, months, or yeares, (the compute thereof, and the beginning of the yeare being different, according unto different Nations) they thought best to settle a generall ac-count unto all, and to determine these alterations by some known and invariable signs; not inscribing thereto any part of causality, but notice and signification; and thus much Isaiah, Nolite timere à signis cæli, and that in Genesis, Vt sint in signa & tempora: Let there be lights in the firmament, and let them be for signs and for seasons.

And for signs and for seasons and for days and for years were the lights of the firmament destined to function—in the opinions of the oldest known schools of "wise men," Gentile as well as Jewish. Light, the object in the production of which the Almighty first manifested his creative power, had existed in chaotic space before the formation of the members of the "heavenly host." The fact was an item of the learning of the Egyptians and Chaldæans as well as Hebrews. And the body of cosmic philosophy imported by Pythagoras into Italy, on his return from his prolonged pilgrinage of learning, presents so many points of resemblance to the Mosaic that the famous Archbishop Ussher thought that it

might be argued that he had conversed with the Jews at Babylon, "for that he transferred many of their Doctrines into his Philosophy, as Hermippus declares in his first Book of Kings concerning Pythagoras, cited by Josephus; and in his first Book of Lawgivers, cited by Origen, which likewise is confirmed by Aristobulus the Jew, a Peripatetic Philosopher." And the special medical influence attributed to the brilliant Dog Star is thus stated, and contradicted, by Browne:

Now from the rising of this starre not cosmically, that is with the Sun, but Heliacally, that is, its emersion from the rayes of the Sunne, the Ancients computed their cancicular dayes; concerning which there generally passeth an opinion, that during those dayes all medication or use of Physick is to be declined, and the cure committed unto Nature, and therefore as though there were any feriation in nature or justitiums imaginable in professions, whose subject is naturall, and under no intermissive, but constant way of mutation; this season is commonly termed the Physitians Vacation, and stands so received by most men: which conceit however generall, is not onely erroneous, but unnaturall, and subsisting upon foundations either false, uncertaine, mistaken, or misapplied, deserves not of mankinde that indubitable assent it finded.

I have already referred to the confusion of ancient items of testimony regarding canicular dates, associations, references, and influences, produced by substitution of heliacal emersion for cosmic ascent-or vice versa, and the progressive modification of our celestial relationships due to the precession of the equinoxes. Sherburne (the translator, and very enlightening commentator, of The Sphere of Manilius) also notices the fact, and adds: "But the greater part of the Antients assign it to the time of the Sun's first entering into Leo, . . . At this day with us according to Vulgar computation, the rising and setting of the said Star is in a manner coincident with the Feasts of St. Margaret (which is about the 13th of our July), and St. Lawrence (which falls upon the roth of August), as this common verse expresses it:

Margaris Os Canis est, Caudam Laurentius affert. The precessional deviation of the slope of our planet's axis has not modified cosmic relations (and their associated dates) much since the days of Edward Sherburne, Esquire; and our current almanacs seem to mean by "dog days" the series of forty diurnal rotations which ends with that of August 11th—the date of the cosmic ascent of the dog star.

The original division of the year—by the celestial lights which had been creatively placed in the firmament as landmarks "for seasons"—is thus indicated by the author of the *Pseudodoxia Epidemica*:

And by this way the Ancients devide the Seasons of the yeare, the Autunne, Winter, Spring, and Summer, by the rising of the Pleiades, denoting the beginning of Summer, and by that of the Dog-star, the declination thereof; by this way Aristotle through all his bookes of Animals, distinguished their times of generation, Latitaney, migration, sanity and uenation; and this were an allowable and generall way of compute, and still to be retained, were the site of the stars as inalterable, and their ascents as invariable as primitive Astronomy conceaved them: And therefore though Aristotle frequently mentioneth this starre, and particularly affirmeth that fishes in the Bosphorus are best to be catched from the arise of the Dog-starre, must we conceave the same a meere effect thereof? Nor though Scaliger from hence be willing to inferre the efficacy of this starre, are wee induced hereto; except because the same Philosopher affirmeth; that Tunny is fat about the rising of the Pleiades, and departs upon Arcturus, or that most insects are latent from the setting of the 7. starres; except, I say, he give us also leave to inferre that those particular effects and alterations proceed

from those stars, which were indeed but designations of such quarters and portions of the yeare, wherein the same were observed: Now what Pliny affirmeth of the Orix, that it seemeth to adore this star, and taketh notice thereof by voyce and sternutation, untill wee be better assured of its verity, wee shall not salve the sympathy.

And Browne then proceeds to point out, with gen-

uinely judicial keenness:

what slender opinion the Ancients held of the efficacy of this starre is declarable from their compute; for as Geminus affirmeth, and Petavius his learned Comment proueth, they began their account from its Heliacal emer-sion, and not its cosmicall ascent; the cosmicall ascension of a starre we terme that, when it ariseth together with the Sun, or the same degree of the Ecliptick wherein the Sun abideth; and that the Heliacall, when a starre which before for the vicinity of the Sun was not visible, being further remoued beginneth to appeare: for the annuall motion of the Sun from West to East being far swifter then that of the fixed stars, he must of necessity leave them on the East whilst he hastneth forward, and obscureth others to the West: and so the Moone who performes its motion swifter then the Sun (as may be observed in their Conjunctions and Eclipses) gets Eastward out of his rayes, and appeares when the Sun is set; if therefore the Dog-star had this effectuall heat which is ascribed unto it, it would afford best evidence thereof, and the season would be most fervent, when it ariseth in the probablest place of its activity, that is, the cosmicall ascent, for therein it ariseth with the Sun, and is included in the same irradiation: but the time observed by the Ancients was long after this ascent, and in the Heliacall emersion, when it becomes at greatest distance from the Sun, neither rising with it nor neere it; and therefore, had they conceived any more then a bare signality in this Star, or ascribed the heat of the season thereunto, they would not have computed from its Heliacall ascent which was of inferiour efficacy, nor imputed the vehemency of heat unto those points wherein it was more remisse, and where with lesse probability they might make out its action.

It must, however, be noted in explanation—not, of course, in justification of the diffusion and maintenance of such blundering opinion and doctrinethat the heliacal ascent would have made its impression on the popular vision, mental as well as physical, long before the early star gazer had attained the scientific equipment necessary for the calculation of the precise date of cosmic rising. The æther, with which the Pythagorean philosophy filled all cosmic space beyond the moon, was free—not being obnoxious to any material disturbances. This latter property enabled it, too, to permeate, without opposition or delay, every form of intervening mattereven the unwholesome aër which occupied the sublunar space around the surface of our own planet, and the whole thickness of our sure and firmly set earth itself. A medium of such subtlety was fairly worthy of composing the substantial essence of the being of the Divinity of a pagan philosopher! Its presence readily accounted for the instantaneous communication between the most distant parts of the cosmos. And, although a purely imaginative production of the heathen philosophical intellect of untold centuries ago, the physicist of the present day tries still to base the (now decidedly uneasy) foundations of his phenomena and his experimental results on this same slippery "quintessence"!

The gradual apparent changes of cosmic relationship due to variation of the direction of the earth's axis had, of course, become familiarly known and scientifically explained before the days of Sir

Thomas Browne:

not) that the site of the fixed starres is alterable, and that since elder times they haue suffered a large and consider-

able variation of their longitudes; the longitude of a starre to speak plainly, is its distance from the first point of numeration toward the East, which first point unto the Ancients was the Vernall æquinox; Now by reason of their motion from West to East, they have very much varied from this point: The first starre of Aries in the time of Meton the Athenian was placed in the very intersection, which is now elongated and remoued Eastward 28. degrees; insomuch that now the signe of Aries possesseth the place of Taurus, and Taurus that of Gemini; which variation of longitude must very much distract the opinion of the Dogge-starre, not only in our dayes, but in times before and after; for since the world began it hath arisen in Taurus, and before it end may have its ascent in Virgo; so that wee must place the canicular dayes, that is the hottest time of the year in the spring in the first Age, and in the Autumne in the ages to come.

This unsettled relationship of cosmic (circumferential) and terrestrial (central) phenomena on which the learned and devout author of the Religio Medici so judiciously dwells in the above quotation was the subject of comment and calculation in the various ages and nations of astronomical culture, and has been kept continuously in view ever since the days of Hipparchus. And in one of his references to the ancient metrical Astronomicon, from which I have already quoted the remarkable verses which contain the account of the Canicula, the critical Salmasius points out that "Manilius, qui in prima leonis parte caniculæ exortum constituit, non sphæram barbaricam, id est, Egyptiacum sequitur, sed vulgarem, et Græcanicam"; and quotes the very definite dictum of Egypt's great royal astronomer, Ptolemy: "Tredecimo kal. Augusti, sol in leone, corus spirat, et canis exoritur." And the importance of this celestial landmark, more especially to the rural resident and agriculturist, in the various known centres of ancient civilization, is well shown by the many references of their most representative poets, and more particularly in association with matters remote from the more busy haunts of men. Thus Germanicus:

Et pernix lepus et procyon et sirius esse. Totiusque canis rapidi vestigia prima. —and the divinely melodious Maro himself:

Candidus auratis aperit cum cornibus annum Taurus, et adverso cedens canis occidit astro.

Browne then proceeds to examine more closely the famous aphorism of the father of medicine, and to trace its probable origin and indicate what must have been its real significance:

But that which chiefly promoted the consideration of these dayes, and medically advanced the same, was the doctrine of Hippocrates a Physition of such repute, that he received a testinmony from a Christian, that might have beene given unto Christ [Qui nec fallere potest nec falli]: the first in his booke de Aere, Aquis & locis, Syderum That is, wee are to observe the rising of Starres, especially the Dogge-starre, Arcturus, and the setting of the Pleiades or seven Starres; from whence notwithstanding wee cannot in generall inferre the efficacie of these Stars, or coefficacie particular in medications: probably expressing no more hereby then if hee should have plainely said, especiall notice wee are to take of the hottest time in Summer, of the beginning of Autumne and winter, for by the rising and setting of these Starres were these times and seasons defined; and therefore subjoynes this reason, Quoniam his temporibus morbi finiuntur, because at these times diseases have their ends, as Physitions well know, and hee else where affirmeth, that seasons determine diseases, beginning in their contraries; as the spring the diseases of Autumne, and the summer those of winter; now (what is very remarkable) whereas in the same place he adviseth to observe the times of notable mutations, as the Æquinoxes and the Solstices, and to decline Medication tenne dayes before and after, how precisely soever canicular cautions be considered. This is not observed by Physitions, nor taken notice of by the people. And indeed should we blindly obey the restraints of both Physitions and Astrologers, we should contract the liberty of our prescriptions, and confine the utility of Physicke unto a very few dayes; for observing the Dogdayes, and as is expressed some dayes before, and likewise tenne days before, and after the Equinoctiall and Solsticiall points, by this observation alone are exempted above an hundred dayes; whereunto alone are exempted above an hundred dayes; whereunto if we adde the two Egyptian dayes in every moneth, the interlunary and plenilunary exemptions, the Eclipses of Sunne and Moone, conjunctions and oppositions Planeticall, the houses of Planets, and the site of the Luminaries under the signes (wherein some would induce a restraint of Purgation of Phlebotomy) there would arise above an hundred more; so that of the whole year the use of Physicke would not be secure much above a quarter; now as wee doe not strictly observe these dayes, so need we not the other, and although consideration bee made hereof, yet might wee preserve the nearer Indications, before those which are drawn from the time of the year, or other calestial relation

(To be concluded.)

A NOTE ON CONJUGAL DIABETES.

By Alfred C. Croftan, M. D., Chicago.

During the last three years I have had the opportunity of observing six instances of diabetes occurring together in man and wife. The first case was discovered by chance, because the wife, fearing that the disease might be contagious, brought her urine for examination. The other five cases were all discovered within the short interval of two years and three months, presumably because, interested by the discovery of the first case, I have since then, whenever possible, examined the urine of the consort of a diabetic for sugar; if no sugar was discoverable in a random specimen, then another test for alimentary glycosuria was made according to the usual method.

The six cases were found among a total of 24I diabetics, i. e., in 2.49 per cent. Inasmuch as forty-seven of the patients with diabetes were not married or had lost their consort, my six instances of conjugal diabetes actually constitute approximately three per cent. of the married diabetics studied.

In looking through the literature on this subject, numerous instances of conjugal or "domestic" diabetes are found. All in all I have been able to collect 162 cases; these are all instances in which the coincidence of diabetes in husband and wife was so striking that the possibility of a contagion was

thought of.

It is interesting to note the varying percentage of such instances that different authors report among the total (married and unmarried, and unknown civil state) cases of diabetes observed during a given period. The highest percentage is reported by Devore, who found six instances of conjugal diabetes among fifty cases, i. e., so high a percentage as twelve per cent. Fumaro among 127 diabetics found fifteen instances, i. e., 11.8 per cent. Lecorché, among 104 cases, six instances, i. e., 5.2 per cent. Leading German authors, it is peculiar to relate, find much smaller percentages and altogether occupy a rather sceptical attitude toward the whole question. Seegen, e. g., found instances of conjugal diabetes only three times among 938 diabetics, i. e., in 0.32 per cent. Senator nine cases in 770 diabetics, i. e., 1.17 per cent. Then there are very many authors y be report one of two isolated cases. Consequently

it is very difficult to establish any reliable data in regard to the general frequency of this disorder. An interesting table has been arranged by Hanriot, who, taking 100 cases reported by different writers, found that these 100 cases occurred among 5,987 diabetics (married and unmarried), and therefore constituted 1.67 per cent. of the total number observed.

In view of the scanty material so far observed, in view of the fact, moreover, that no attempt has been made to classify the various glycosurias that are all grouped under the name diabetes, it is altogether premature to venture an explanation of the possible causes underlying the peculiar phenomenon of con-

jugal or domestic diabetes.

That one is dealing in most of the cases with more than a coincidence is clear; such a thing may occur by chance; but in my series, for instance, in which glycosuria was regularly looked for in the consort, the proportion of instances discovered is far too great to warrant the inference that this is the case. One must think of common errors of alimentation obtaining in a family, or of common errors of living, of exposure to common nervous, mental, and emotional influences. One must think finally of contagion. Syphilis and malaria can produce glycosuria; also certain other contagious and infectious disorders of known type that cause vascular degenerations in important organs (liver, pancreas, nervous system) concerned in sugar metabolism.

It is not impossible that other infectious agents of unknown character and origin may be concerned in the transmission at least of certain types of diabetes. This subject is well worthy of further study; it is a corollary of the contagious theory of gout that is gaining many adherents. To deny the possibility of a contagious diabetes on the one hand is precarious; to affirm its existence on the other altogether prema-

ture.

These facts and considerations at least warrant further investigation and the collection of more elaborate and more exact statistics. They have induced eminent authorities to commit themselves strongly in favor of the *reality* of conjugal diabetes.

My object in publishing this note is to stimulate interest in this important inquiry. "If you find glycosuria in one of your patients, look for it in the

mate."

100 STATE STREET.

REPORT OF A CASE OF EXTENSIVE EMPHY-SEMA COMPLICATING TUBERCULOSIS OF THE LUNGS AND URINARY ORGANS.

By W. D. Hennen, M. D., New York.

CASE—Mr. T., aged fifty, was referred to me February 6, 1908. He was an alcoholic to the extent of ten whiskeys a day, complained of dyspnœa and palpitation upon exertion. Six months previous he had fainted, and on coming to vomited clotted blood mixed with undirested food.

Six months previous he had fainted, and on coming to vomitted clotted blood mixed with undigested food. On visiting him I found a large, emaciated man showing the superficial vinous enlargement of the chronic alcoholic. Chest, emphysematous. Heart, displaced to one and one half inches beyond nipple line, liver enlarged one and one half inches downward. Left lung apex showing common signs of tuberculous consolidation. Pulse 140, breathing 40.

The triconducted data are sure closs under tes cherits, recherches are a constant? Meeting the second of May, 1904, Xo. 12.

Temperature 102.6° F. No sputum. Urine, 6 ounces in twenty-four hours.

February 8th, urine loaded with tubercle bacilli, exam-

ined by Dr. Sondern.

February 9th, cystoscoped and attempted catheterization of ureters. Findings: The prostate was prominent laterally. The roof of the bladder contained two round tuberculous ulcers the size of a split pea each. The orifice of the right ureter was in the hollow of a triad of ulcers each the size of a nickel. The ureter itself was constricted one and one half inches above its bladder termination. The opening of the left ureter was cedematous and surrounded by an irregular conglomeration of ulcers, the ureter itself having a stricture one inch high. It is to be noted that there had been no bladder symptoms referable to a condition in which fully one quarter of the bladder mucosa was eroded.

February 12th, summoned to the patient's house because of "swollen jaw." I found the following conditions: A swelling running from the third rib to symphysismenti, from the anterior axillar line to outer sternal line. The swelling gave the typical emphysematous crackling. Temperature 102° F., pulse 100. Some slight sputum. There had been no paroxysm of cough or any other cause for

this condition.

February 21st, Dr. Janeway in consultation. The swelling had spread to the eyebrows, closing one eye, down both

arms to the wrists, and to the symphysis pubis and crests of the ilia. Sputum increased, pus, blood, four ounces. March 1st, the swelling closed both eyes. The eyelids were bulging and hard to touch, white from pressure. Enormous swelling over parotids, giving appearance of a cobra. The whole thorax and abdomen were puffed, giving an increase of five inches to the thorax. The sputum had increased to twelve ounces in twenty-four hours; there was no blood, only elastic fibres, pus, and epithelial cells, no tubercle bacilli. The patient felt well, slept and ate well, had no dyspnœa, despite a pulse of 100, and a remitting temperature of 102.5° F.

March 5th, the swelling began to go down, first leaving the face and neck. From this date on the patient ran steadily down hill; periods of delirium supervened, and after a very bad night, on March 9th, he died at 4

o'clock in the morning.

206 WEST EIGHTY-FOURTH STREET.

THE DOCTOR AS A PUBLIC EDUCATOR.*

BY FRANK VAN FLEET, M. D., New York.

Surgeon to the Manhattan Eye, Ear, and Throat Hospital, Eye Department; Chairman of the Committee on Legislation of the Medical Society of the State of New York.

The subject of the doctor as a public educator is not a phase of our professional life which physicians, as a rule, are inclined to consider very seriously, if, indeed, they consider it at all. They are not different in this respect from other people, for we all manifest a spirit of indifference which, if we were to think over and appreciate the possible consequences of, would arouse us to a sense of our responsibilities and make us wonder how we could so long have been neglectful of them.

It is not necessary to look far for reasons for this

apparent indifference.

The age in which we live, and the government and other conditions under which we exist, ensure to all citizens a degree of comfort and ease which does not seem, on the surface at least, to call for particular exertion on our part beyond that required to earn our livelihoods and care for our families. So, as citizens, we are generally content to let the politicians make our laws, the paid educator look after the mental development of our children, and the press mould the current of public opinion, while

we look complacently on, satisfied that our outward evidences of prosperity and growth indicate a healthy condition, which does not call for interference on our part. We, as medical men, are content to do as others, and allow things to drift, and, as I have already said, we are not more remiss than our fellows in other callings.

You do not hear of doctors entering public life as often as other people, it is true, although in Europe, on the Continent especially, and in the South American republics as well, we do read of men in public life having the title Doctor, and one often wonders just what kind of doctors they are. Even in our own country doctors do enter public life, perhaps oftener than we think. In the State of New York at the present time, of the two hundred and one men composing our State legislature, seven are licensed physicians, and doubtless, if we had the lists of the legislatures of other States, we might find our profession fairly well represented in

the law making bodies.

It is not my purpose to-night, however, either to advocate or criticise the entrance of physicians into the political arena. Doubtless the presence of seven physicians in the legislature of any State could be made a great, and even a controlling influence in shaping the course of medical legislation in that State, but to the outside observer, and even to one who may have had opportunity for closer observation, there is nothing to indicate that the presence of the seven physicians in the legislature of New York exerted any influence, one way or another, on the bills introduced in that body having to do with the public health.

I think I can say without fear of contradiction that in the thirteen years that I have been connected with the committees on legislation of the State or county medical societies, I cannot recall a time when the presence of a physician as a member of the legislature had the slightest influence in any way.

By this I do not wish to be understood as saving that physicians cannot exert an influence in shaping public opinion, for that is not what I mean. believe the medical profession is capable of exerting the greatest influence in this direction. Indeed, I am of the opinion that the medical profession could easily control the enactment of laws affecting public health if we of the profession were willing to do it.

Our profession is held in the highest esteem by the majority of the people of this country, and it would be surprising if this were not the case, for any other feeling toward a profession which, in the main, does so much for the common good, would indicate a lack of gratitude which is not natural to

humanity.

We must, however, bear in mind that our calling is not a business, and the man who enters the ranks of the profession as one enters upon a business career, with no other object in view but the commercial one, actuated by no other thought than that prompted by the commercial spirit, is not only doomed to disappointment, for he will find the time spent in preparation altogether out of proportion to the financial return, but he will also miss that keen sense of satisfaction with his work which comes only to the one who, beside the commercial aspect, glories in the philanthropical possibilities of his pro-

^{*}An address delivered in part at Fraunce's Tavern, in New York City, at the eleventh annual dinner (one hundredth meeting) of the Practitioners' Club of Jersey City, June 9, 1908.

The world, too, rates us as a profession of philanthropists and benefactors, and its estimation of our

position is very high.

I believe people generally experience a feeling of regret when they see a doctor magnifying the commercial side of his profession, or entering into pursuits which have no direct bearing or connection with his professional work.

The world does not rate a man high as a physician who proclaims himself to be a politician, and while it will accord to the practising physician the greatest possible regard for his opinions on questions of public health, it is not willing to be guided by him when there is a possibility that his opinions may be influenced by political considerations.

People are willing to be guided by us along medical and public health lines because they think we have knowledge which they do not possess, and that we, as a profession, are not actuated by selfish motives. They look to us for enlightenment, or, in other words, they look to us to guide them, and

they ought not to look in vain.

This age in which we live is an age of education; indeed, the people are education crazy. They are clamoring for information, and if they cannot obtain it from reliable sources they will get it from sources which are unreliable.

It is astonishing how earnestly and intently they will read the advertisement of the patent medicine man and listen to the haranguing of the quack. They listen to the specious arguments of the various kinds of "paths" when they know that all

"paths" lead to the grave.

They listen to the man who calls himself by a peculiar name, or who employs a peculiar method of treatment, not because they prefer that kind, but because that sort of a person is willing to talk to them. I am glad to note that our profession is coming to see the logic of this, and that many of the leaders of the regular profession are manifesting a greater willingness to talk to the public on these vital questions than heretofore. It is gratifying, indeed, to read the remarks of the incoming president of the American Medical Association, as well as the editorial article in the New York Medical Journal of recent date, on this very subject. We should be public educators, and I hail the coming day when our medical societies will give public lectures on public health subjects, as the Medical Society of the County of Kings has been doing during the past winter months.

Let us briefly consider some of the subjects on which, in my opinion, the medical profession should enlighten the public. There are many such subjects which I shall not attempt even to mention in the brief time at my disposal, but with your permission I shall speak only of a few which are not local in their character and which are engaging the public

attention.

I would like to speak of medical education because I believe it is a subject the public should know about, for if there were ever unjust laws on our statute books surely those governing the practice of medicine are glaring types.

Of course, the purpose of these laws, like the purpose of all law, is to protect the public with the test the least possible hardship on those who

would practice the healing art, but not only do the medical laws of this country fail in the first instance, for they do not protect the public, but they impose on men who would comply with them an amount of hardship which make them practically prohibitive to students who are not financially independent.

Medical laws do not protect the public, because special laws are being constantly enacted which permit privileged classes to practise medicine in special lines, thus exposing the people to practitioners who have not the knowledge sufficient to enable them to do the work these special laws authorize them to do. In New York there are now two such laws, one regulating the practice of chiropody and the other the practice of optometry. These laws are on the statute books to-day because the State Department of Education is willing that they should be there, and there is not a particle of doubt that any body of men who will advance a peculiar theory of practice, or a peculiar method of treatment, or who for any reason are not willing to comply with the law as it exists to-day, can, if they will keep at it long enough, and secure sufficient political influence, secure an enactment which will enable them to evade the requirements of medical practice act. And it will continue to be so as long as members of the legislature and the Department of Education have incorrect notions of the purposes of our medical

Surely a medical law which permits newspapers to advertise tuberculosis and other nostrums, prepared by men who have no medical qualifications whatsoever, and who in the majority of cases have no knowledge of the diseases they advertise to cure, cannot be said to afford protection to the public.

At the same time the requirements for the men who desire to enter the medical profession are being increased until now, in nearly every State, they are so great that it is impossible for one to comply with them and receive a license to practise until he is about twenty-seven or twenty-eight years of age, so that, if it takes five years longer to build up a practice sufficient for one's support, the man who desires to become a physician finds it impossible to meet the requirements unless he has an independent income or is fortunate enough to find a backer with sufficient faith in him to advance the necessary funds. The time is approaching when a poor man, or the son of a poor man, will find it impossible to enter upon the study of medicine with the idea of practising it, and personally I do not believe this is for the best interests of the community.

Another unjust feature of our medical laws is the disparity of the laws in different States, which compel reexaminations before physicians can go

from one state to another to practice.

I believe there are no laws on our statute books more unjust, and even absurd, than our medical laws, and I have long been of the opinion that the public would be as well protected if they were all repealed, which, indeed, is what happened in the State of New York in 1847.

Another subject on which the voice of the profession should be heard with greater force than has been the case is the physical defects of school chil-

dren and the control of our public schools.

The public school is the bulwark of American

citizenship, and has probably had more to do than any other single force in making our country what it is to-day.

These free institutions are designed to dispense knowledge alike to all, the rich and the poor, the high and the low, the intelligent and the stupid.

Here all are supposed to meet on equal ground, and without fear or favor, partiality or favoritism, receive the knowledge dispensed so freely to all.

While the fact has long been known that some children seem to appreciate all that is provided for them and some seem to treat their opportunities with indifference, it has not always been generally conceded that often the apparent indifference of some children is due to causes which, while beyond the child's control, are such that they can be remedied.

The subject of the physical defects of school children is of great magnitude and one fraught with greater possibilities than nearly any other subject now before the public mind. It is too large a subject to treat in detail at this time, and I will deal with it only briefly from the standpoint of an ophthalmologist.

A thorough examination of the children in our public schools would reveal the fact that many of them, variously estimated at from thirty to sixty per cent., have eyes so defective as to seriously handicap their possessors in the competition of life which begins in the school room.

Observation and experience have demonstrated that children who are apparently stupid, sometimes refractory or even seemingly incorrigible, become bright, active, docile, and sometimes prize scholars when defective eyes are corrected with glasses and the children are put on an equal footing with their more fortunate companions.

So enthusiastic have school teachers and educators generally become over the possibilities in these cases that they are ready to go to what seems to be ridiculous extremes in suggesting remedies. In the city of New York they have advocated the appropriation of public moneys for the equipment of school houses with facilities for the examination and treatment of children's eyes, some even urging the unlimited distribution of free eye glasses, to be paid for out of the city treasury.

The medical profession should step in here and urge caution. It is no part of the duty of the government to supply free eye glasses to people who need them any more than it is to supply free food and clothing, unless the people are too poor to pay for them. Nor is it any part of the function of the departments of education to conduct dispensaries for the treatment of physical defects of school children.

Money appropriated for such purposes can be better employed in securing the better lighting of school rooms, better ventilation of school houses, in providing better styles of desks and seats, of improving books, and so on, thereby lessening the production of physical defects, leaving the treatment of such defects to family physicians and others who are competent to deal with them.

Another subject to which we should give more attention in a public way, as a profession, is the

prevention of tuberculosis.

A disease which causes upward of fifteen thousand deaths in one year in a single state alone is one

which should surely receive our attention, and is receiving it, too, but not to the extent it should.

An army which in time of war lost fifteen regiments would receive deserved censure, yet in the State of New York fifteen regiments of men, women, and children, of one thousand each, go down to death each year from this dread disease alone, and the saddest part of it is that they are preventable deaths. It seems to me our profession should be more in evidence than it is in this matter. It would be most unjust to declare that the medical profession is doing nothing in this matter, but it is not doing its full duty. The law which has just been passed in New York, providing for the reporting of tuberculosis and the proper protection of healthy persons from its contamination, was prepared and advocated by an organization which does not include a single physician on its board of managers. It is true that this organization did ask and receive the aid of our profession in securing the enactment of this law, but I believe the initiative should be with us.

Another subject which engaged the attention of legislators, physicians, and the public generally, in New Jersey and New York, during the last legislative sessions of these two states, was animal experimentation. And we have not heard the last of it.

This agitation for the restriction of animal experimentation—or really, its abolition, for that is what the agitators desire—was one of the most peculiar of which I have knowledge. It was overcome, however, by the medical profession refuting the charges brought against it, and the passage of laws which would have been inimical to the progress of medical science were prevented.

There never was a more striking example of what can be done by the medical profession than in this instance.

Various large and influential societies of women held meetings for the purpose of endorsing the antivivisection movement, and, without exception, I believe, after hearing the statements of facts made by members of our profession, voted not to support the movement.

It is surprising what misstatements were made by the advocates of this movement. That men will declare from the public platform that animal experimentation has not added in any way to the knowledge we possess of diseases and their remedies, after scientific men whose names are synonymous with progress have declared that without such experiments it would have been impossible to discover much that has in this way been positively demonstrated, passes all comprehension.

Not later than May 24th we have the newspapers announcing that the American Society for the Prevention of Cruelty to Animals has issued a statement that rabies is an exceedingly rare disease, if indeed, it really exists at all, despite the fact that the Board of Health has records of twenty-eight authentic deaths from this disease in one year in that city alone, and one of the pathologists of the Department of Agriculture at Washington is quoted as authority for the statement that the disease is increasing in prevalence.

The stories of atrocious cruelties practised by some of our most eminent and scholarly investi-

gators have been denied time and again, but, notwithstanding this, and that court decisions make it plainly evident that, under existing law, societies for the prevention of cruelty to animals have authority to enter and inspect places where such cruel practices may be perpetrated, and that under these laws punishment can be meted out to such offenders, antivivisectionists clamor for more restrictive laws, and will never be satisfied until laws so restrictive in their requirements as to be prohibitive are enacted. Sad it is, too, that lawyers, who must know the consequences of their actions, advocate such laws.

There is a crying need that something be done to educate the public along public health lines.

Can you imagine a governor of a great State attaching his signature to a measure, thereby creating a law, making doctors of opticians, and giving them the right to treat all sorts of defects of vision with glasses, regardless of the causes, and requiring of such special doctors only a knowledge of optics?

Can you imagine a man calling on physicians to introduce a preparation with a patented name, declaring it to be a sure cure for tuberculosis?

Can you imagine a great newspaper taking up an antivivisection crusade in retaliation for a medical society's successful efforts to compel that newspaper to obey the law?

And can you imagine the public allowing such things to continue if there was a proper knowledge

of what it all means?

No! Lamentable ignorance on the part of legislatures and governors is the only way to account for their utter disregard for the rights of the people they are sworn to protect.

A degraded intellect which places money above every other consideration in this world is the only explanation for the quacks and some of the news-

papers doing as they do.

And yet these are the existing conditions, which would not be tolerated if the people of this great country had the knowledge they might have and should have.

Gentlemen of the medical profession! It is up to us, as physicians, to see to it that questions relating to public health are properly placed before the people, that they may have knowledge to enable them to act intelligently.

The people are with us, and when they act as if they were not it is because they have not properly understood the pros and cons of the subjects in

We are members of a great profession left to us in all its beauty and dignity as the result of the self sacrificing efforts of those who have gone

We have received this priceless heritage and ours it is to pass on, unsullied and untarnished, to our children and successors.

Our predecessors built on firm and sure foundations. Let us add our mite to the building of a glorious and perfected superstructure.

Well has the poet sung:

"Not gold, but only men, can make As their great and strong Their who for truth and justice sake Stand fast and suffer long. see the work while others sleep, Who stand when others fly. They plant the nation's pillars deep And raise them to the sky.

We have met here to-night in Fraunce's Tavern to celebrate the one hundredth meeting of a club of medical men. Your secretary has told of what has been done in the years of your club's existence, and you have done well.

In this building, perhaps in this very room, on December 4, 1783, George Washington delivered his farewell address to the officers who had fought with him in the war which made these United States of

These men faced problems, and, not counting the cost, worked them out to a satisfactory conclusion, but these men faced problems not greater than the problems we are facing, and there is no more fitting time and place than now and here for us to resolve that we, too, will face our problems, and with the pluck and endurance which characterized these ancestors of ours, work them out to their conclusions, remembering always that no great question is ever settled until it is settled right.

Let us again listen to the poet, who says:

"Mourn not for the vanquished ages, With the great and glorious men, Who dwell in history's pages And live in the poet's pen. For greater days are before us, And the world has yet to see
The noblest deeds of this old earth In the men who are yet to be.'

Our Readers' Discussions.

A SERIES OF PRIZE ESSAYS.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:
LXXVII.—How do you treat acute articular rheumatism?
(Closed July 15, 1908.)
LXXVIII.—How do you treat varicose ulcer? (Answers due not later than August 15, 1908.)
LXXVIII.—How do you treat acute coryza? (Answers due not later than September 15, 1908.)
Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred xwards.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXV has been awarded to Dr. P. A. Smithe, of Enid, Oklahoma, whose article appears below.

PRIZE QUESTION NO. LXXV.

THE TREATMENT OF CHOLERA INFANTUM.

By P. A. SMITHE, M. D., Enid, Oklahoma

The treatment of cholera infantum, both prophylactic and curative, should be based entirely on the ætiology, which is the feeding of food unsuited to the age or food altered by fermentation or putrefaction so as to become unfit for digestion by young children. Predisposing factors are chilling, over heating, irregular or too frequent feeding, and excessive humidity of the atmosphere, and against these the mother must be taught to bring to bear an

"enlightened intelligence."

Prophylaxis should begin at birth, and should first take the form of an effective veto of any kind of diet except the natural one, the breast. Should artificial feeding become absolutely necessary, cow's milk from a *clean source*, suitably modified with water and a little lime water, without sterilization or pasteurization, should be used during the first year. Pasteurization is only allowable temporarily, as in cities when for any reason the reliable supply fails. During the second year cream of wheat, rolled oats, barley gruel and rice (well cooked and salted), mashed baked potatoes, bread, butter, toast and soft eggs may be added sparingly. The practice of bringing a baby to the table with the family to eat what it fancies is a prolific cause of trouble. Whenever possible mothers should receive detailed instruction in feeding, together with the reasons therefor, and the most important points well emphasized.

Treatment of the acute attack.—The child should be kept in a crib or bed, never carried or rocked, as this causes an extra drain in the strength. Clothing should not be too abundant, preferably of light flannel, and the abdomen should be covered with a flannel protector. If the case is a severe or neglected one, a reliable nurse will often do inestimable good. She will give the mother a feeling of security, which in the absence of the physician she may lose, and, losing, fail to carry out his directions

properly at a critical time.

Give first castor oil, one teaspoonful if under three months; two, between three and six months; a tablespoonful if over six months. If rejected (usually with the undigested contents of an overfilled stomach) wait a half hour and repeat. If again rejected give it ice cold. Give nothing by the mouth for two hours after the first retained dose, then allow as much water as the child wishes every two hours; not oftener, as the stomach needs a complete rest. Allow no food but the water for twenty-four hours, and in the severe cases for forty-eight hours. is when your nurse will come in handy, as it is hard to convince the mother that the child will not starve to death, which it will in no case do. Have the napkins numbered and dated, as they are your When the stools become infrequent, best chart. free from curds, green mucus, and bad odor, which they will if the described rule has been carried out in detail, the time has come to feed, and not till then.

Begin feeding at four hour intervals with water allowed half way between. For a child of three months or under, take a teaspoonful from the upper ounce of top cream taken from a quart bottle of good milk, after it has stood on ice if possible ten hours. Add two tablespoonfuls of water and two teaspoonfuls of lime water for each feeding. On the second day, if all goes well with the stools, give this feeding every two hours. Later increase the amount of food by using more of the upper ounce of top cream and more water, but keep the proportion of proteid low by using only the upper ounce of top cream, using more bottles when necessary. For a child of six months begin feeding exactly as with

the three months' child, except use two teaspoonfuls of the upper ounce of top cream with three tablespoonfuls of water and three teaspoonfuls of lime water to each feeding. Increase the amount of the feeding and of the constituents after two or three days, in the same manner as for the three months' child, and after a week or so use the upper two ounces of top cream, diluted with water, as before.

Children from one to two years old should be fed at four hour intervals, but a cereal gruel, preferably pearl barley, cooked three hours, should replace the modified milk. It should be given in three or four ounce feedings and gradually increased. Cream of wheat, rolled oats, or rice may be substituted.

Chronic cases under one year old do better on condensed milk, diluted with sixteen volumes of boiling water, but this diet must not be a permanent one, or nutritional disorder will supervene.

If choleraic symptoms are prominent at the start, or if there is much tenesmus, I instill normal salt solution into the rectum by means of a soft rubber catheter attached to a fountain syringe, with ten

to twelve inches fall.

To capitulate: Cholera infantum is a food disease and should be treated by emptying the intestinal tract, and then feeding only what the child can digest with a weakened gastric and intestinal mucosa. Opium or its derivatives only postpone disaster. Intestinal antiseptics are worse than useless, as they are bound to irritate the stomach. Rational treatment cannot consist in drugging, but in a painstaking, detailed assisting of Nature.

Dr. Frederic H. Wilson, of New York, says:

Cholera infantum is a very acute gastrointestinal disease, and owing to its sudden onset and the severity of its attack, it forms one of the most important diseases which the pædiatrist is called upon to handle. Owing to its more frequent occurrence in the summer months it was formerly thought to be a disease caused by hot weather, but I do not believe such to be the case. It often follows a more or less protracted attack of ileocolitis, and I believe it to be due wholly to the formation in the intestinal tract of toxines thrown out by bacterial growths, fostered by fermentations. These toxines must be of a most virulent character, causing, as they do, so serious an effect upon the entire system. Children, recovering from an attack of cholera infantum, are usually found to have lost weight in greater amount than from any other disease of similar duration.

I shall describe a prophylaxis for this affection, though I realize that the sudden onset usually makes the case an emergency one. Still I think that in view of the frequency of a previously existing ileocolitis, the physician should always keep in mind, while dealing with an attack of the latter, the possibility of the onset of cholera infantum and should therefore bear in mind its prophylaxis. This consists particularly in not thinking too lightly of the "summer diarrheea," for which he has previously been called. The feeding of the infant, when an attack of cholera infantum is thought likely, should preferably be from the breast. Water given the child should always be boiled and cooled against the ice. Be careful not to overfeed the infant recover-

ing from an ileocolitis, and never attempt to wean it until a long time has elapsed. The patient should be put in a well ventilated, darkened room, and should be allowed to see but one or two people, who

should avoid exciting the child.

Now for the active treatment of an attack of genuine cholera infantum. Consider the clinical picture. A child, weak and puny, vomiting every few minutes and retching more or less constantly. The bowels move perhaps more frequently than vomiting occurs, and the stools have become mere mucous. Tenesmus is nearly constant. The pulse is feeble, the breathing shallow and irregular, the temperature ranges from 102.5° to 105° F., and the litle one is almost too exhausted to cry. Naturally the first thought is thoroughly to empty the stomach and intestines of the irritant poison which is causing the trouble. The stomach can only be treated satisfactorily by means of lavage, and this should be immediately performed. Often one washing will be sufficient to stop or at least diminish the vomiting. Colon irrigations are next in order, and the keynote of success here is the height of the irrigation. Practically the entire large intestine should be flushed out, though without too much hydraulic pressure. The fluid should be allowed to pass in and run out freely, as the child is not to be made to retain the water. Normal salt solution is probably the best for the irrigation and Conklin (1) recommends that the irrigation with salt solution be followed with one of tannic acid, gr. 20 to the pint, to "render inert the soluble poisonous proteids which may remain." I have never tried this, chiefly because the tannic acid has never been obtainable just when wanted, but I think it might be an excellent procedure.

Secondly; the child having so copiously discharged fluid from its gastrointestinal tract, is naturally extremely thirsty and will take with avidity almost anything offered by the well meaning but unwise mother. This is immediately vomited and no relief for the thirst is obtained. I think that no fluid should be given by mouth, save that the child may be allowed to suck small pieces of ice held in a fold of clean gauze. The thirst, however, can be greatly relieved by the introduction of normal salt solution into the subcutaneous tissues. Surgical cleanliness in this little operation should be strictly observed, and the fluid may be introduced into the tissue of the abdomen preferably, or the thighs. I do not advise injecting it into the back of buttocks because the child is usually lying on its back, and the pressure of the body may increase its discom-The amount of solution injected should be carefully measured, and several ounces at a time may be given. This may be repeated at one or two hour intervals. It is most important to avoid injecting air with the fluid, and this is more difficult to avoid than in giving ordinary hypodermic injections. All food should be withheld for from ten to twenty hours, and then feeding should be begun gradually, exceedingly light at first and slowly increased, using breast milk, or barley or albumin water.

The reduction of temperature and stimulation of the heart are also of prime importance. The former is best accomplished by the cold pack or full bath, together with the application of ice to the head

The full bath, if given, should be first tepid and gradually cooled to about 80° or 85° F. by introducing ice. Evans (2) uses ice cold water irrigations of the colon to reduce the temperature, but I think the method is rather heroic and would be contraindicated in many cases. For stimulation, brandy by mouth or hypodermically is probably best. It should be given in ten to twenty drop doses, diluted several times. Ether and camphor are recommended by Holt (3) and are excellent, but have the disadvantage of frequently causing a painful lump to remain at the site of injection for some days afterward. The use of antipyretic drugs cannot be too strongly condemned. In fact, drug therapy is use-less, if not harmful, in this condition. In rare instances the administration of bismuth subnitrate, gr. viii; or bismuth subgallate, gr. ii, have seemed beneficial, but the good may well have come from the other parts of the general treatment.

The absorption of the toxines from the intestines in cholera infantum forms one of its principle dangers. Their effect is a poisoning of the entire nervous system and a strong reaction on the heart. Something must therefore be done to counteract or antidote this poisoning, and here morphine seems to have the best effect. Atropine, too, is useful, both these drugs being given in very small doses and, necessary, hypodermically. The dose of morphine for an infant one year old may be from gr. 1/80 to 1/50 and that of atropine sulphate from gr. 1/800 to 1/600. The dose may be repeated if necessary

after a few hours.

The child recovering from an attack of cholera infantum is a most delicate case to handle, requiring minute attention to detail and constant watching. If a city child, he should, if possible, be sent to the country. The diet must be very gradually increased and little or no reliance should be placed on any of the baby foods. Cow's milk, modified to suit the case, should be allowed only after a considerable lapse of time after the cessation of the attack. The child should be kept in the open air and sunshine as much as possible and not allowed to become fatigued.

A résumé of the treatment may be given as fol-

lows:

Prophylaxis: Careful attention to preceeding illness; especial care in feeding during convalescence; appropriate surroundings, as dark, ventilated room,

Active treatment: Remove irritant from stomach and intestines; supply fluid to body to replace that lost; reduce temperature; stimulate heart; counteract absorption of poisons from intestines.

After treatment: Send to country; use great care in resuming diet; open air and sunlight; avoidance

of over exertion.

RIFFRENCES

- Discases of Children, p. 381.

Dr. Sidney J. Sondheim, of Reading, Pa, writes:

When a case of true cholera infantum comes under the care of a physician it means that he has before him a battle with a vicious and rapid working enemy, one which demands prompt and decisive action with careful personal supervision.

The first measure is to stop all food. Give at once a hypodermic injection of morphine sulphate, gr. 1/75; atropine sulphate, gr. 1/600. Strychnine sulphate, gr. 1/100, can be added if the child is weak. Repeat if necessary. This measure serves to overcome severe pain, tenesmus, and vomiting, thus quieting the child. It also relieves spasmotic condition of intestines, not causing retention of fæces and toxine, but prepares the way for thor-

ough cleansing to follow. The next measure is the thorough but gentle lavage of the stomach with normal saline solution. Before withdrawing the tube introduce through the same fziii to fzvi of castor oil. Compress tube above by fingers and quickly withdraw, preventing as far as possible the oil on top of tube from touching tongue. The stomach having been cleansed and the small intestines taken care of by castor oil, we now look to the large intestines. High rectal enemata of normal saline solution (viii to xvi f3) are now administered, the buttocks being held together and the solution retained as long as possible. measure not only acts as a cleanser, but furnishes fluid in readily absorbable condition, which the child badly needs. The enemata should be frequently repeated; every four hours in first twelve hours, and according to the severity of the case more or less frequently in the next thirty-six hours. vomiting continues equal parts of lime water and cinnamon water may be given by mouth.

The child now has a thoroughly cleansed gastrointestinal tract, and we must now prevent, or if already present, allay, inflammation of the tract, overcome diarrhœa, and support the child's strength. Bismuth subnitrate, gr. x to xv; salol, gr. ii, in chalk mixture acts well as astringent, antiseptic, and mechanical healer of the tract.

Return to food must be very gradual, and the child's stools and general condition carefully ob-

In breast fed babies thirst may be relieved by barley water. When returned to breast, the periods of feeding should be very short and interval between feedings long. Both, if child's condition is favorable, can be modified according to the judgment of the physician.

In bottle fed infants, when diarrhæa and other symptoms subside, begin with skimmed milk, boiled, and diluted with three quarters barley water. crease the amount of milk gradually, and cautiously increase the fats. A tonic may be given to child

to hasten recuperative process.

Pure food, carefully prepared, fresh aid, exercise. and bathing are the essentials of prophylaxis.

Dr. L. C. Freeny, of Pittsville, Md., remarks:

Assuming that the case presents itself as a true cholera infantum, prophylaxis being out of the question, we look first to the milk supply as the source of trouble. If bottle fed, is the cleanliness of the bottles and milk assured? We really have here a ptomaine poisoning to deal with, and it may be highly necessary to change the methods, the milk. or both. Next we look at the proportion of the fats and the proteids as possible sources of irritation, their reduction being called for almost always.

Cases occurring in breast fed children are uncommon, being then generally due to overfeeding, and a change to cow's milk is hazardous and not to be undertaken unless the mother is suffering from some acute infectious disease, tuberculosis, cancer, and perhaps menstruation.

It is of prime importance that the food ingested be reduced to a minimum, withholding it entirely for at least twenty-four hours. At the expiration of that time teaspoonful doses of beef juice every two or three hours should be tried tentatively. This is easily digested and avoids the possible introduction of more toxines from the milk supply.

When ordinary milk feeding is resumed, say in a week's time, one third the usual quantity is sufficient, bearing in mind the sources of supply, clean-

liness, fats, and proteids.

As soon as seen, the child receives calomel, gr. 1/10, every half hour until one grain is taken. This is followed by two teaspoonfuls of castor oil.

We have here a paretic bowel, made so by toxines, which increases serous transudation from the vessels and wall. The evacuations vary greatly in number and character. They are greenish, yellowish, brownish, or almost colorless; reaction alkaline. The odor is sometimes very foul, but generally it is not very offensive, especially in the late stage of the disease.

While we should reduce the amount of food ingested, we must not overlook the important fact that the fluid lost by serous purging must be replaced. This can be accomplished by giving boiled water by the mouth, or by irrigating the stomach and intestines. Should danger seem imminent from this cause alone, saline transfusion might be practised.

When vomiting is so persistent that all food is rejected, we should give a copious, high colonic injection of normal salt solution, and, after a reasonable interval, a nutrient enema of white of egg, whiskey, and water. This enema must be warm, and not contain more than one and one half ounces. It can seldom be given more often than three times a day, on account of intolerance of the bowel.

Aside from calomel and castor oil, drugs seem to do little good. I have discarded opium except in combination with starch water as an injection, giving it then only when the stools are frequent, large, and watery, and accompanied with much pain. Two to five drops of the tincture of opium with one half ounce of starch water injected high in the bowel seems to do good sometimes, but must be used with

If, as seems entirely probable from the symptoms, these toxines are due to bacillary production, it would be highly desirable that some intestinal antiseptic be found to prohibit their production. I know of nothing of this nature that has the slightest

For the high fever present a tub bath, beginning with the water at 90° F., gradually reducing to 80°

F., serves the purpose well.

My main reliance in the treatment of this disease is in high colonic injections of normal salt solution, the temperature of which should be from 95° F. to 100° F. These are repeated every eight hours. It would seem that a bowel constantly emptying itself

would not need washing out, but this is not borne out in my cases. The irrigations remove a variable quantity of intestinal débris, intestinal toxines not yet absorbed, and replace lost fluid. They also flush the kidneys, and thus remove toxines which have been absorbed into the blood current.

Should collapse threaten, strychnine sulphate, 1/60 gr., must be given hypodermically. This is

a suitable dose for a child two years old.

If the child survive the attack one week and does not get well, we then have a subacute marasmic condition which may last for weeks, terminating as

a rule in an enterocolitis.

If the means, as described, are visibly failing, speaking now of a case that has survived the attack a week, our hope lies in salt air and a continuance of the colonic flushing. The child must be kept out in the open air all the time, no matter how weak or desperate the condition. It is really astonishing how some apparently hopeless cases recover at the seashore, and without any other treatment than the irrigations. It is due in part doubtless to the abundance of cool, fresh air. But there is some-peculiar tonic action exerted by the salt laden air. It is particularly unfortunate that the seashore is out of the reach of so many of these little patients.

(To be continued.)

Correspondence.

LETTER FROM TORONTO.

The Annual Meeting of the Ontario Medical Council.— Criminal Abortion and the Newspapers.

TORONTO, July 8, 1908.

During the week ending July 11th the Ontario Medical Council held its annual session in Toronto. Dr. W. Spankie, of Wolfe Island, the retiring president, delivered the annual presidential address, reviewing the work of the Council for the past year. In his address he referred at considerable length to the attacks recently made upon the Council by some of the public press of Ontario, particularly the Toronto Globe, which for the space of a year or so has been taking upon itself the task of pointing out to the Medical Council its path of duty. That particular path of duty lay along the highroad of the crime of criminal abortion, of which there have been recently in the Ontario criminal courts several cases against members of the Ontario College of Physicians and surgeons. While the press was apparently calling upon the Council to institute proceedings against these members of the profession, of which the Globe alleged there were several known in Toronto, the Council rested on their oars, content in their belief that the proper persons to institute proceedings against alleged criminals, in whatever class of society, were the law officers of the Crown. But of this more anon.

The president dealt in his address with other matters of importance. With regard to the question of reciprocity with Great Britain, seeing that Quebec and Nova Scotia have already reciprocity with the home country, he said it was one of great importance. He stated that there were now on the Ontario Register 3,807 members in good standing Permanent quarters had been purchased during the past year at a cost of \$21,000, and as soon as building material and labor cheapened it was the intention to go on and build suitable accommodations. Another subject that should engage the attention of the Council was that of a readjustment of the electoral divisions. The following officers were elected for the ensuing year: President, Dr. S. H. Glasgow, of Welland; vice-president, Dr. E. A. P. Hardy, of Toronto; registrar, Dr. John L. Bray, of Toronto; treasurer, Dr. H. W. Aikins.

At the recent examinations of the Council, the examiners had "plowed" about sixty-five per cent. of the writers. It was thought either that this was unfair or else there was something wrong with the system of education. On motion of Dr. Britton, of Toronto, a special committee was appointed to look

into the matter and report.

The special committee on a five year curriculum appointed last year reported that, in view of the fact that the various teaching institutions had not yet had time to complete the details of their fifth year course, the committee recommended that no action be taken with regard to specifying additional work.

The names of 189 physicians had been struck off the Register during the past year for nonpayment of the annual \$2 assessment. In most of these cases the men had left the province or could not be found.

A special committee was appointed to consider the advisability of securing reciprocity between the College of Physicians and Surgeons of Ontario and the General Medical Council of Great Britain, as provided for in the Medical Act of Great Britain. Dr. S. H. Glasgow, Dr. J. A. Temple, and Dr. E. A. P. Hardy, of Toronto, were appointed the executive

committee for the ensuing year.

The introduction of the following motion and the discussion thereon formed the most interesting part of the proceedings, at least to the public press apparently, for all pertaining to it was fully reported: The attention of this Council having been recently called to the prevalence of crime against the unborn, that when the detective (of the Council) becomes aware of such a case, he be instructed to lay the matter before the Prosecutions Committee, who will, after careful inquiry, pass the evidence, when deemed advisable, on to the Discipline Committee for action." Special names were mentioned in the debate on this resolution, names of some who were recently implicated before Ontario courts of law in the matter of criminal abortion: and the editor of the Toronto Globe, a Presbyterian minister, who has for some time been pressing upon the Council their line of duty in these cases, came in for comment, favorable and unfavorable. There has been a great deal of newspaper talk with regard to certain cases which have occurred throughout the province, and it has not been yet clearly shown that the newspaper in question was divested of all political bias in some of these cases. It seemed to labor under the delusion for a time that the Ontario Medical Council was a criminal court, and that the duty of the Council was to hunt down the criminals and

punish them by depriving them of their license to practise. forgetting that the law officers of the Crown were the duly authorized parties to take any such proceedings in the medical profession as in all other walks of life. Recently, however, the *Globe* has modified its demands on the Council, and now pins its faith to a clause in the Medical Act which practically goes to show that the Council should deal with men who are guilty of infamous or disgraceful action in a professional respect. It has gone out of the criminal cry business. Well, when this selfsame Council has sought before now to discipline some of its members for infamous and disgraceful action or conduct in a professional respect, the Toronto Globe and practically all the other lay press poured hot shot into the Council for daring to take away from a man the means of making bread and butter for his family. One thing seems to be quite clearly brought out in the whole controversy, and that is this, that the Council must in all cases deal strongly with every one adjudged guilty by the courts of law in these cases. They will be wise men who proceed with all due caution in the case of any one adjudged not guilty. The Ontario Medical Act requires that a charge against a member of the Ontario College of Physicians and Surgeons of unprofessional conduct of any character shall be signed by four practitioners before the Council shall undertake to investigate. Be it so, especially in the case of criminal abortion. Where or how are four men to become possessed of absolute facts so as to warrant them in impeaching a confrère before the medical court? Every practitioner here as in other places has most probably heard of some one performing these nefarious practices; but it is only hearsay. He has no absolute proof. The Toronto Globe, through its editor, states that there are several in the city of Toronto alone who perform abortions; and upon hearsay evidence calls upon the medical profession to clear its skirts. The physicians of Canada feel that the Crown officers should call upon the editor of the aforesaid newspaper, or the Ontario Medical Council, the guardian of the profession throughout the province, should call upon this self appointed pedagogue of doctors' morals to make good his statements in a court of law, and that he should be made to name his men and prefer his charges against them, and them alone, and not against the entire medical profession throughout the province at large.

Therapeutical Hotes.

The Treatment of Pulmonary Tuberculosis.— La Clinique for July 3, 1908, publishes a lengthy excerpt from a volume entitled La Pratique théra-peutique, by Courtois-Suffit and Tremolières, published by O. Doin, Paris, giving rules for the treatment of persons afflicted with pulmonary tuberculosis. Of the hygienic treatment exposure to air is considered fundamental. It should be uninterrupted night and day, and all the time. To guard against cold a flannel chemise should be worn and hot water bottles placed next the feet if necessary. The outlook of the invalid's chamber should be to the south, varied sometimes by an eastern or western exposure, according to the season of the year and the country. To be prohibited is confinement in closed rooms, especially where large crowds are gathered in theatres, cafés, stores, etc. Exposure to the rays of the sun should be avoided. A phthiscical subject should never walk abroad in the sunlight without the protection of an umbrella.

Contrary to the general belief, exercise of the hody is not beneficial for consumptives, for the reason that it accelerates tissue combustion. Mental and physical fatigue, bodily exercise, and in particular that of the chest and upper parts of the body, are to be formally interdicted. Walking alone is to be permitted. Such walking exercisé should, however, he easy and on a level surface, and preferably after meals. The number and duration of the walks should be regulated by the physical condition of the patient, bodily weight and temperature being taken into consideration. Any diminution of the usual bodily weight necessitates abstention. Absolute repose must be imposed on patients when feverish symptoms develop, and any increase of temperature above 100.4° F. should be taken to constitute fever in the tuberculous subject. Baths should not be taken too frequently, and they should not be too warm or be indulged in for too long a period at one time. A bath at a temperature of 95° F. for a period of from ten to fifteen minutes is permissible, and it should be followed by a good rubbing.

Local revulsive treatment is employed to overcome pain in the chest, this consisting of the application of mustard leaves, mustard poultices, or the tincture of iodine. As general treatment nutritives like codliver oil and yolk of egg should be prescribed. Glycerin and arsenic are useful in certain conditions. The soluble phosphates are also recommended, calcium lactophosphate or calcium chlorhydrophosphate being used in 7 to 30 grain doses, administered in elixir, syrup, or wine.

Antiseptic agents that are eliminated by the bronchial tubes are of value. Creosote, alone or combined with calcium phosphate, sodium arsenate, etc., may be given either in pill form or in oily solutions and in enemata, as in the following forms:

| R Creosote,gr. iss |
|--|
| Calcium phosphate,gr. ss |
| Pulverized soap,gr. iss |
| M. ft. pil. |
| Oily solution: |
| R Creosote, |
| Codliver oil,Oii |
| M. et sig.: One tablespoonful twice or three times daily |
| Enema: |
| B Olive oil, |
| Creosote, |
| Wine of opium, |
| M. |
| |

Two tablespoonfuls of this mixture added to a glassful of warm water are emulsified with the yolk of an egg to form an enema.

NEW YORK, SATURDAY, JULY 25, 1908.

OBSTACLES IN THE WAY OF THE PRAC-TITIONER.

We would call particular attention to Dr. Frank Van Fleet's article, published in this issue of the Journal, entitled The Doctor as a Public Educator, a theme on which the author finds himself in accord with the president of the American Medical Association and with others who advocate competent instruction of the general public in regard to medical matters. Dr. Van Fleet's long connection with legislative affairs in the State of New York as they affect the medical profession, a connection in which he has displayed zeal, tempered with a genuine desire to promote the general welfare, gives to his utterances an ex cathedra quality which could hardly be surpassed. It is not our present intention to comment on all the topics touched upon by Dr. Van Fleet; indeed, we must on this occasion restrict our remarks to a subject indicated in the following paragraph:

At the same time the requirements for the men who desire to enter the medical profession are being increased mitl now, in nearly every State, they are so great that it is impossible for one to comply with them and receive a license to practise until he is about twenty-seven or twenty-eight years of age, so that, if it takes five years longer to build up a practice sufficient for one's support, the man who desires to become a physician finds it impossible to meet the requirements unless he has an independent income or is fortunate enough to find a backer with sufficient faith in him to advance the necessary funds. The time is approaching when a poor man or the son of a poor man will find it impossible to enter upon the study of medicine with the idea of practising it, and personally I do not believe this is for the best interests of the community.

The difficulties arise partly in the medical schools, which, strange to say, seem to plume themselves on their increasing success as obstructionists, and partly in the State examinations. As for the colleges, more and more of them are requiring as a preliminary the possession of a high degree of academic attainments. Now, we do not in the least question the value of a thorough preliminary education, and we should be glad if every medical matriculate had at the outset of his professional studies the advantage of a degree in arts, with all that it ought to imply, but too frequently does not; but we have grave doubts as to the wisdom of insisting that the young man who wishes to enter upon the study of medicine shall have had the costly opportunities necessary to such a possession.

We know that there are in the faculties of some of the schools that have lately added the requirement in question individuals who look upon it with misgivings, and they are men who not only are learned in medicine, but have also had such experience in teaching and such facilities for estimating the elements that make for the welfare of the profession as to give to their opinions almost the weight of finality. What they chiefly fear, and with good reason, in our opinion, is that the rigid requirements will deprive us in the future of many men who would unquestionably add lustre to any high calling. There is certainly something in the feeling that the doctor, like the poet, is born, not made.

As regards the State examining boards, we look upon their examinations as generally better calculated to bring out a candidate's capacity to cram than to ascertain his real fitness to practise medicine. The degree of knowledge of chemistry, bacteriology, ophthalmology, and other more or less recondite branches of knowledge necessary to enable a man to practise medicine creditably is not by any means the grade that will make him a proficient chemist, bacteriologist, ophthalmologist, or specialist in any other branch. This, we think, is too often lost sight of. Then there is the hampering lack of reciprocity in licensing between one State and the others, not complete, to be sure, but still so pronounced as to work a real hardship in numerous instances, both to individuals and to the profession as a whole. We hope to see this remedied within a few years.

MEDICAL MEN AS DETECTIVES AND PROSECUTORS.

A rather remarkable state of things in the province of Ontario is related by our Toronto correspondent (see page 170). Some of the newspapers of Toronto, it seems, are urging the Ontario Medical Council to punish licensed practitioners of medicine for having practised criminal abortion. Now.

any punishment that the Council could inflict, as we understand matters, would be by a revocation of the license, and then only after conviction in a court. At least, we suppose that such a course would not be undertaken prior to a judicial conviction. But, in addition, the Council are told by the newspapers in question that it is their duty to prosecute men suspected of the offense, and not leave that function to the law officers of the Crown.

Now, it is generally thought that medical censorship, far from being neglected by those who have it in charge, too often swells to the dimensions of persecution. A man was once severely disciplined in New York for having professed to be able to pass an instrument into the larynx; another was publicly censured for having consulted with a homeopath (the "consultation" having really consisted in the heinous offense of attending the homocopathic physician's wife in confinement); and in London a few years ago another was made to suffer for what was looked upon as practising ablation of the clitoris without due cause. All of us have long been heartily ashamed of those persecutions, for such they now clearly seem to have been, and we mention them simply to show that in censorship the profession has been anything but negligent in the past. We hope it will not soon be led again into such pernicious activity. Of course the cases we have adduced and prosecutions for criminal abortion are not parallel, but, so far as the power of any medical body goes, they have the common element of censorship.

Medical men, whether individually or in some corporate capacity, are not now quite so ready as they once were to act the part of the official or volunteer "smelling committee," and we believe that our Ontario brethren are not going to precipitate themselves into the rôle. As our correspondent well says, any newspaper editor who suspects a medical practitioner of practising criminal abortion ought to furnish to the proper law officers such information as may lead to a judicial investigation; simply to hound medical officers on to the infliction of so mild a penalty as the revocation of a license, after an investigation necessarily hampered by unusual difficulties, is to deal very gently with persons who, if they are guilty, are among the most loathsome of malefactors.

Abortionists are notoriously hard to convict, but it is not to any unwillingness of medical men to testify that the difficulty is due. To expect them also to prepare the case is asking too much. If some of our county societies and boards of health do occasionally dabble in detective work, they do not render it at all more congenial to practitioners of medicine in general.

THE HISTORY OF MEDICINE.

Interest in the study of the history of medicine grows apace. It is a sign of a broadening of culture in the student of medicine that he should interest himself in the links of the chain of human experience which reaches into the well of the dim past. Goethe was unduly pessimistic when he wrote: "All professional men labor under a great, disadvantage in not being allowed to be ignorant of what is useless. Every one fancies that he is bound to transmit what is believed to have been known." In the mad rush for the acquirement of new knowledge we often miss the compensations that might come from quiet meditation on that which has been known and long since forgotten.

The history of medicine, as a codified and coordinated branch of study, has been difficult of approach, save to those well acquainted with the German tongue and for whom three thick volumes have had no terrors. The histories of Haeser, Pagel, and Puschmann have no rivals as to size or scholarly qualities. What has been needed for a beginner has been a condensed but comprehensive work, and fortunately one of that sort has just appeared from the pen of Julius Pagel, so well known as the foremost of medical historians.1 To those familiar with the comparative tables of some universal histories, the method adopted in these "Time Tables of Medical History" will not prove unique. The author has been able to present in some twenty-seven tables a comparative chronological development of the history of medicine.

In the first table, prehistoric medicine, the medicine of the savage, is taken up; then follows a table rich in comparative data on the history of medicine of the older civilizations—from 2000 to 800 B. C.; a third gives a brief presentation of the classic period of Hellenic culture; then follows that of the Middle Ages, with the Byzantine and Arabic periods, the medicine of the monks, the rise of the Salerno school, and the scholastic periods of the thirteenth and fourteenth centuries, which flowed into the renaissance of modern times. The names of Vesalius, Paré, and Paracelsus stand out in the sixteenth century, while the English school comes to its full flower in Harvey and in Sydenham in the following era. The names of the eighteenth and those of the nineteenth centuries are too numerous and well known to cite, but all the salient features are here, arranged so that with one glance the whole situation may be appreciated. For the student of medical history such a résumé as is presented in these Zeittafeln is invaluable.

IJ. L. Pagel, Zeittarein zur Geschehte der Meinem Berlin, ic S.

THE PERSISTENCE OF ERROR.

That "truth crushed to earth will rise again" is generally conceded, but the undiscerning public does not seem to realize that error is frequently quite as persistent. Dr. William Osler has recently had ample proof of this, for both the British and the American press have made his sixtieth birthday, which, according to the newspapers, occurred recently, the excuse for cartoons and satirical comments innumerable based on his reported dictum that all men should be chloroformed at sixty. The mere fact that Dr. Osler did not lay down such a proposition-and this has been established beyond question-seems not to have had any deterrent effect on the cartoonists and paragraphists. Many of them must have known that the quotation was apochryphal, but the occasion was too good to be wasted through a mere blind obedience to truth. The story was well invented if not true, and the entry of Dr. Osler into the race for the Lord Rectorship of the University of Edinburgh in competition with the Right Honorable George Wyndham and the Honorable Winston Spencer Churchill, both younger men than himself, gives zest to the jokes.

Dr. Osler is not alone, however, in suffering from misquotations, for noted authors, from Milton to Mark Twain, suffer with him. In Lycidas we find the line "To-morrow to fresh woods and pastures new." The reading of "fields" for woods has been almost universally adopted by the general public. What Sydney Smith really said was: "There is humor in a Scot's skull, but the only instrument by which it can be extracted is-a corkscrew," which is both more true and more witty than the phrase "approbation from Sir Hubert," which has become "praise from Sir Hubert." Niels Horrobow opens a chapter on The Snakes in Iceland by the phrase "There are no snakes in Iceland." Some careless borrower made the quotation read "Ireland," and nothing less than a Papal bull would now correct the popular error.

Scribes and historians do not hesitate to invent apt phrases ex post facto, as has been done in Dr. Osler's case and in that of the Old Guard, which will die, "but never surrender" for the balance of time, despite the evidence of Victor Hugo in Les Misérables. Altogether, we fear that Dr. Osler's case is hopeless and that he will go down to posterity as the doctor who advised chloroform for all men at the age of sixty, but who, fortunately, did not take his own medicine. Incidentally it is not without interest to note that the press has erred in prematurely celebrating Dr. Osler's sixtieth birthday, which, according to Who's Who, will not occur until 1909.

THE HEALTH OUTLOOK.

Before the National Conference of Charities and Correction, held in Richmond, Va., on May 11th, the chairman of the Committee on Public Health, Dr. Walter Lindley, of Los Angeles, Cal., delivered an address entitled The Nation's Outlook for Health. It appears in the June number of the Southern California Practitioner, of which Dr. Lindley is the editor.

Dr. Lindley first devotes attention to the Oriental plague, giving a graphic picture of the East Indian mortality from that disease in recent years and noting the importance of exterminating rats and their fleas, which play such a preponderating part in spreading the pestilence. Flies and mosquitoes, too, he reminds us, are other insects against which radical measures must be taken. He warns us anew of the facility with which certain diseases may be communicated to man from the dog and the cat. He sees in the present readiness to engage in the work of exterminating noisome insects and attending carefully to the health of the necessary domestic animals a hopeful sign of the subjugation of several infectious diseases.

Dr. Lindley sees hope also in certain therapeutical advances, such as Wright's "vaccine" therapy, Bier's artificial hyperæmia, and Flexner's serum for the treatment of cerebrospinal meningitis, as well as in the temperance movement, the increase of national forests, the multiplication of trained nurses, and recent Congressional legislation concerning pure food and drugs. With regard to cancer he says: "This field is awaiting the advent of a new Jenner, Pasteur, or Koch." On the whole, Dr. Lindley's appreciation of the outlook is cheering.

THE FAD ABOUT OVEREATING.

Sir James Crichton-Browne has several times of late made brave pronouncements anent popular convictions as to medical and physiological affairs. Now, according to the press dispatches, he has publicly declared against the fad about overeating; and it was none too soon. It has recently become very common for men to remark, generally over a generous repast, that undoubtedly we all eat too much. For the most part such a statement is purely academic, we suppose, for we have never observed that the belief was strong enough in the preacher's breast to lead him into any striking curtailment of his own indulgence.

Generalizations spring readily to the tongue, especially to that of the man who thinks he knows something of which his neighbor is in blissful ignorance, and what wiseacre is there nowadays who

does not know the ins and outs of physiological chemistry, hygiene, nutrition, heredity, and many another branch of knowledge that the lifelong student finds puzzling? For our part, we have always demurred to the dogma which would screw a man's consumption of good and toothsome food down to the minimum required to maintain his physical efficiency as measured by calories and such like abstract standards. Such teaching is repugnant to all but the stingy. We are glad, therefore, that the distinguished English alienist has thus given the authority of his great name to our conviction.

Obituary.

FRANK HUGH MONTGOMERY, M. D., of Chicago.

While yet in the prime of life—he was about forty-five years old—Dr. Montgomery met death by drowning on July 14th. He was a physician and medical teacher of eminence, a public spirited citizen, and a man held in high esteem by the profession and by all who knew him. His chief professional work was in the field of dermatology. At the time of his death he was the assistant secretary of the faculty of the Rush Medical College (University of Chicago) and associate professor of skin, genitourinary, and venereal diseases in that institution.

Rems Items.

Changes of Address.—Dr. Saul Knopf, to 561 Willoughby Avenue, Brooklyn.

A Department of Sanitary Science and Hygiene has been established at Cornell University. The course will be opened on October 8th by an address by President

An American Surgeon in the Olympic Games.—The American revolver team, of which Dr. Reginald H. Sayre, of New York, is the captain, won first place in the competition in revolver shooting.

A New Hospital in Neenah, Wis.—Plans have been submitted for a new hospital in Neenah, Wis., which is being presented to the city by Mr. Charles B. Clark. The hospital will cost about \$100,000.

The Destruction of Mosquitoes in Cuba forms the subject of an interesting memorandum presented to Governor Magoon by nis chief sanitary officer, Major J. R. Kean, of the Medical Corps of the Army.

Rockaway Beach Hospital and Dispensary.—Work on this institution has been begun, and plans have been made for the laying of the corner stone on August 9th. A three days celebration will be held on August 9th, 10th, and 11th, for the benefit of the hospital, which will include a "tag day"

Dr. William P. Spratling, for nearly fourteen years the medical superintendent of the Craig Colony for Epileptics, Sonyea, N. Y., has been elected to the chair of nervous diseases and physiology in the College of Physicians and Surgeons, Baltimore, and will move to that city in a few

Contagious Diseases in Chicago.—During the week ending July 11, 1008, there were reported to the Department of Health 235 cases of contagious diseases, as follows: Diphtheria, 62; scarlet fever, 45; measles, 75; chickenpox, 5; typhoid fever, 6; whooping cough, 8; tuberculosis, 26; smallpox, 1; minor diseases, 7. As compared with the preceding week, the number of cases reported of all diseases except typhoid fever and diphtheria, has decreased; these show an increase of one case each.

The San Francisco Relief Home for the Aged and Infirm.—We learn from Charities and the Commons that this institution has been opened and is now crowded to its full capacity. It is situated on the grounds of the old almshouse, and has been erected by the San Francisco Relief and Red Cross funds, at a cost of \$300,000.

A Medical Weekly in Esperanto is soon to be established in Hungary, according to the Budapest correspondent of the Lancet. The journal is to be devoted to Slavonic medical affairs. The various Slavonic dialects differ so widely that some ready means of intercommunication between the different localities was needed.

To Exterminate Flies in Massachusetts.—The Massachusetts State Board of Health is planning a campaign against flies, which it is thought will last at least a year and involve an expenditure of \$200,000, which sum has been appropriated for that purpose. The projectors of the campaign confidently predict the complete extermination of

files in the State.

The Mortality of Connecticut.—During the month of June, 1908, there were reported a total of 1,135 deaths from all causes, which was 68 less than in May, 90 less than in June of last year, and 76 less than the average number of deaths during the month of June for the preceding five years. The death rate was 13.6 for the large towns, 12.8 for the small towns, and 13.4 for the whole State.

The Mortality of Chicago.—During the week ending

The Mortality of Chicago.—During the week ending July 11, 1908, there were reported to the Department of Health of the City of Chicago 510 deaths from all causes, as compared with 410 for the preceding week and 483 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.28. The principal causes of death were: Apoplexy, 8; Bright's disease, 42; bronchitis, 9; consumption, 57; cancer, 28; convulsions, 5; diphtheria, 6; heart diseases, 40; intestinal diseases, acute, 52; measles, 2; nervous diseases, 23; pneumonia, 36; scarlet fever, 7; suicide, 13; typhoid fever, 1; violence (other than suicide), 49; whooping cough, 5; all other causes, 127.
Clean Food as Well as Pure Food for the Capital.

Olean Food as Well as Pure Food for the Capital.—
Dr. William C. Woodward, health officer of the District of Columbia, has instituted an active crusade against unclean restaurants and lunch rooms in Washington. In the business section of the city there are a number of small lunch rooms, which have been complained of on the score of a lack of cleanliness, and an investigation showed that in many of these, and in some of te larger restaurants as well, the food was prepared and served under the most unsanitary conditions. This is all to be changed, as Dr. Woodward will have closed those places which fail to comply with the requirements laid down by him as to cleanliness. He will be aided in the work by two additional food inspectors, whose appointment was provided for at the last session of Congress.

The New York Police Take Part in the Anti-Noise

The New York Police Take Part in the Anti-Noise Crusade.—The police commissioner of the city of New York has issued a general order instructing the police force to put a stop to all unnecessary noise. In the course of the order the commissioner says: "The police are directed to suppress the shouting of street hawkers of all kinds; all unnecessary shouting and yelling; unnecessary blowing of steamboat or factory whistles; roller skating on the streets or sidewalks to the interruption and interference of traffic; whistling of peanut roasters; unnecessary blowing of whistles or horns on motor cycles or automobiles; letting the exhaust escape from motor cycles and automobiles without being properly muffled; yelling of the "old clothes" man; yelling of carriage barkers at theatres and hotels; flat wheels on street cars; barking of dogs."

Precautions Against Tuberculosis at the New York Stock Exchange.—Prompted, no doubt, by the inquiry regarding the danger of tuberculosis infection through telephones, which was recently addressed to the Postmaster General of Great Britain by a member of Parliament, the New York Stock Exchange recently had its four hundred employees examined for evidence of tuberculosis. Three of the employees were found to have symptoms of the disease, and these have been sent to the mountains to recuperate at the expense of the exchange. Some three hundred telephone operators employed by members of the exchange are now being examined by a physician detailed for that purpose by the Board of Health. Out of the first thirty examined three gave evidence of tuberculous infection, and their respective employers have withdrawn them from service in the exchange and assumed the cost of their proper treatment.

A New Edition of Gray's Anatomy.—It is announced by the publishers, Messrs. Lea & Febiger, of Philadelphia, that a new edition of Gray's Anatomy is soon to appear. In the work of revision, which has been in progress for about two years, Dr. J. Chalmers Da Costa and Dr. Edward A. Spitzka have been associated. Dr. Spitzka has rewritten the portion relating to the nervous system, illustrating it with seventy of his own drawings. The revision of the entire book has been thorough and complete, and in its new form the book will undoubtedly take again the high place which it formerly held in the esteem of the medical profession, both as a textbook and as a book of reference.

Vital Statistics of New York.—During the week ending July 11, 1908, there were reported to the Department of Health of the City of New York, 1,516 deaths, 979 marriages, and 3,009 births. Of the total number of deaths, 739 were in Manhattan, 127 in the Bronx, 549 in Brooklyn, 78 in Queens, and 23 in Richmond. The annual death rate in 1,000 of population was 17.88 for the entire city, 17.13 for Manhattan, 20.23 for the Bronx, 19.19 for Brooklyn, 17.50 for Queens, and 15.65 for Richmond. The total infant mortality, under five years of age, was 600, of which 359 were due to diarrhœal diseases. There were 147 deaths due to pulmonary tuberculosis during the week. There were 156 deaths by violence, 58 from sunstroke, 12 from suicide, 4 from homicide, and 82 from accidents. One hundred and twenty-five still births were reported.

The American Medical Missionary College, which is situated in Battle Creek, Mich., and Chicago, Ill., was incorporated on July 3, 1895. The sole purpose of the college is the training of physicians for medical missionary work, and no students are accepted except those who intend to devote their lives to missionary work. At the time the college was established no similar institution existed, and it is said that this is the first and only successful venture of the sort in the history of medical missionary education. It is nonsectarian. Since the organization and incorporation of the institution 343 students have been admitted, and 177 have been graduated. The college is a member of the Association of American Medical Colleges, and its entrance requirements and curriculum meet the requirements of the American Confederation of Reciprocating, Examining, and Licensing Medical Boards.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending July 18, 1008:

| 20, 2,00. | Ini | V 11 | luly | 18 - |
|------------------------|--------|------|--------|-------|
| | Cases. | | Cases. | |
| Tuberculesis pubers | | 107 | 481 | 173 |
| Diphtheria | 235 | 33 | 203 | ~ = |
| Measles | 431 | 1.4 | 312 | 13 |
| Scarlet fever | 187 | 16 | 156 | 1 4 |
| Smallpex | | | | |
| Varicella | 47 | | 35 | |
| Typhoid fever | 7.2 | 10 | 50 | 8 |
| Whooping cough | 18 | .3 | 25 | - 1 |

| Total. | 1 140 | 188 | 1.200 | 2.1.2 |

Changes in the Faculty of the College of Medicine of Syracuse University have been made as follows: Dr. Frank P. Knowlton, associate professor of physiology, has been made professor of physiology; Dr. H. S. Steensland, associate professor of pathology and bacteriology; Dr. H. D. Senior, associate professor of anatomy, has been made professor of anatomy, the been made professor of anatomy; Ernest N. Pattee, M. S., professor of chemistry in the College of Liberal Arts, Syracuse, N. Y., has been made a member of the faculty of the College of Medicine; Dr. Richard H. Hutchings, medical superintendent of the St. Lawrence State Hospital, Ogdensburgh, N. Y., has been appointed lecturer in psychiatry; Dr. Ralpha, N. Y., has been appointed lecturer in orthopædies; Mr. Charles V. Morrill, recently assistant in zoology in Columbia University, New York, has been appointed lecturer in histology and embryology.

Medical Inspection of Schools in Chicago.—During the term of the relative the chool year ending force 20, 1008, the medical inspectors of schools examined 406,019 children, excluding 12,240, or 3 per cent., on account of contagious, infectious, or parasitic diseases. The principal of the contagions of the contagions, 1,680; mensles, 1,250; mumps, 368; impetigo contagions, 1,680; mensles, 1,250; mumps,

360; pediculosis, 1,644; purulent sore eyes, 334; scabies, 860; scarlet fever, 410; tonsillitis, 2,556; tuberculosis, 22; whooping cough, 265; affections of less importance, 1,348. Vaccination was performed on 47,875 school children, and every pupil in the public and the leading parochial schools was examined as to vaccinal status. One hundred medical men were employed in this service. During the last two weeks of the school year a physical examination was made of 4,188 children, 2,214 of whom were found to be defective and were referred to their family physician for treatment.

Changes in the Curriculum of the College of Medicine of Syracuse University.—It is announced that, commencing in 1909, students entering the College of Medicine of Syracuse University must have satisfactorily completed one full year, and on and after October, 1910, two full years, in a science or arts course in a college recognized by the Regents of the State of New York, and in that course and in their preparation for it, a competent course in physics, chemistry, Latin, one modern language and biology must be included. The equivalent of this requirement, that is, evidence of having passed college examinations for admission to the sophomore or junior class in a recognized college by a student possessed of a medical student certificate from the State Educational Department, will be accepted. Hereafter all chemistry, except applied chemistry, will be taught in the new Bowne Chemical Laboratory of the College of Liberal Arts, instead of in the College of Medicine as heretofore.

Personal.—Dr. Fred W. Thyng, of Boston, has been appointed assistant in anatomy in the University of Maine.
Dr. Bertram H. Buxton, professor of pathology in the Cornell University Medical School, and director of the department of experimental pathology, sailed for London re-

partment of experimental pathology, sailed for London recently, where he intends spending the summer. A gold medal was recently presented to Professor Ramón y Cajal by his many friends and admirers throughout Spain. The medal was presented informally, as Professor Cajal objected to a public ceremony.

M. Henri Becquerel has been appointed permanent secretary for the physical sciences at the Paris Academy of

Sciences.
Dr. Timothy J. Reardon, of Boston, sailed from New York for Bremen on July 14th. He intends to devote the summer to inspecting the principal hospitals of Europe, and will spend some time in the new Municipal Hospital in Vienna, which is said to be the largest and best equipped hospital in the world.

A Clean Milk Exhibit at Washington.—The New York Committee of the International Congress on Tuberculosis are making arrangements to make a clean milk exhibit at the International Congress on Tuberculosis, which meets in Washington, D. C., from September 21st to October 12th. Mr. Nathan Straus is preparing for the exhibit a duplicate of the pasteurization plants erected by him in Heidelberg, Brussels, and Berlin, and there will be a small working dairy, with tuberculin tested cows, skilled attendants, and sanitary utensils, shipping cases, and all the necessary appliances for the marketing of clean milk. An excellent opportunity will thus be afforded for a comparative study of pasteurized milk and milk not pasteurized, but clean. The exhibit will also include photographs of dairies, statistical charts, Petri plates of the bacteriology of milk, and illustrations of tuberculin tests for cattle. Among those who are cooperating with the committee in the preparation of this exhibit are Mr. W. W. Law, Jr., the Hon, Seth Low, Mr. V. Everitt Macy, Commissioner Pearson, Professor Moore, of the State Veterinary College, and Professor Stocking, of Cornell University.

The Health of Philadelphia.—During the week ending July 11, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 34 cases, 7 deaths; scarlet fever, 19 cases, 1 death; chickenpox, 8 cases, 0 deaths; diphtheria, 66 cases, 6 deaths; cerebrospinal meningitis, 3 cases, 1 death; measles, 95 cases, 7 deaths; whooping cough, 39 cases, 5 deaths; pulmonary tuberculosis, 104 cases, 28 deaths; pneumonia, 32 cases, 20 deaths; erysipelas, 6 cases, 1 death; puerperal fever, 2 cases, 1 death; mumps, 4 cases, 1 death; cancer, 26 cases, 31 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 7; diarrheea and enteritis, under two years of

age, 107; dysentery, 1; cholera morbus, 4. The total deaths for the week numbered \$385, in an estimated population of 1,532,738, corresponding to an annual death rate of 19.80 in 1,000 of population. The total infant mortality was 214; under one year of age, 181; between one and two years of age, 33. There were 32 still births, 17 males, and 15 females. There was only a trace of precipitation. The temperatures registered over 80° on five days. There were 29 deaths from heat and sunstroke, 19 adults and 10 minors.

The Fifth Pan-American Medical Congress.—Among the papers which will be presented at this congress, which is to be held in Guatemala, Central America, on August 5th to 10th, are the following: Plan for a Pan-American Institute of Tropical Medicine, by Dr. J. Fred Mayer, of New Orleans; Insane Hospital Annex Reformatory and Treatment Sanatorium for Invalids and Demifious, by Dr. C. H. Hughes, of St. Louis; Hyoscine-Morphine Anaesthesia, by Dr. Emory Lanphear, of St. Louis; Present Views of Sanitary Labor and the Immigrant Question of Central America and the Antilles, by Jackson Smith, Esq. of Cincinnati, Ohio; Medical Education, by Dr. Gaynor, of New York; Teaching of Tropical Medicine in the United States, by Dr. J. C. Wilson, of Philadelphia; Beriberi, by Dr. Maximilian Herzog, of New York; Urethral Transplantation, by Dr. J. D. S. Davis, of Birmingham, Ala.; The Use of Eserine Salicylate in Connection with Abdominal and Pelvic Surgery, by Dr. Daniel H. Craig, of Boston, Mass.; Penetrating Wounds of the Abdomen, by Dr. Randolph Winslow, of Baltimore; Relation of General Surgery to Operative Gynæcology, by Dr. Wiley Broome, of St. Louis, Mo.; Head of the Pancreas in Gallstone Disease, by Dr. Herman Tuholske, of St. Louis, Mo.; Some Conditions Demanding Exploratory Laparotomy, by Dr. Dyer F. Talley, of Birmingham, Ala.; My First Experience with Appendicitis Complicating Pregnancy, by Dr. A. L. Wright, of Carroll, Ia.; The Indications for Cholecystectomy, by Tw. William Jepson, of Sioux City, Ia.; Some Special Surgery of the Uterus and Broad Ligaments, by Dr. Henry P. Newman, of Chicago; The Preparation and After Treatment of Abdominal Section, by Dr. Henry T. Byford, of Chicago, Ill.; Operative Treatment in Retrodisplacements of the Uterus in Relation to Subsequent Pregnancy, by Dr.

Channing W. Barrett, of Chicago.

American Public Health Association.—The thirty-sixth annual meeting of this association will be held in Winnipeg, Manitoba, Canada, on Tuesday, Wednesday, Thursday, and Friday, August 25th to 28th, inclusive. According to the preliminary announcement which has just been received, the subjects selected for discussion at the general meetings include the following: Water, sewage, typhoid, sociology of the Middle West, the relation of state and provincial boards to municipal boards and local health officers, housing problems, the extermination of rats, methods of securing general vaccination, measures to promote the health and safety of school children, national and state pure food legislation, hookworm disease, malarial fevers, and health problems of the Canadian provinces. The Section in Vital Statistics, in addition to special papers by registration officials, will consider the adoption of certain rules of statistical practice by which registration work will be guided in the future. The nomenclature and classification of diseases and causes of death will also be considered in detail in anticipation of a possible revision of the International Classification in 1910. The first meeting of the association will be held on Tuesday morning at 10 o'clock, and after the opening ceremonies will adjourn. The general sessions will be held on the afternoons of Tuesday, Wednesday, and Thursday, forenoons, and will hold evening sessions if it is found necessary. The headquarters of the executive committee will be at the Royal Alexandra Hotel. Information concerning local arrangements may be obtained from Dr. E. W. Simpson, chairman of the local committee of arrangements, Winnipeg, Canada. The officers of the association are: President, Dr. Richard Lewis, of Raleigh, N. C.; first vice president, Dr. Gardner T. Schwarts, of Providence, R. I.; second vice president, Dr. Charles A. Hodgetts, of Toronto, Canada; third vice president, Dr. Manuel Iglesias, of Vera Cruz, Mexico; secretary, Dr. Charles

- t. Endocarditis,
 2. The Use of Fresh Animal Sera in Hæmorrhagic Conditions,
 3. A Typhoid Carrier Fifty-two Years after Recovery,
- 4. Obliterating Endarteritis: Types and Their Surgical Importance, By Charles F. Painter.
- The Use of Fresh Animal Sera in Hæmorrhagic Conditions.-Leary says that it was early recognized by physiologists that the contact of blood with fresh serum or tissue juices hastened coagula-tion. Weil brought out the facts that the blood serum of horses, rabbits, and beef creatures, as well as human serum, had the power of controlling hæmorrhagic processes by increasing the coagulability of the blood; that beef serum was too toxic for ordinary use; that the serum used should be less than two weeks old; that a dose of 15 c.c. intravenously or of 30 c.c. subcutaneously would obtain results in most cases; that the use of serum locally at the point of hæmorrhage favored clotting; that the increased coagulability of the blood persisted for a period of from fifteen days to several weeks. His studies in hæmophilia satisfied him that in the hereditary type of the disease the results were at the best temporary, that repeated injections were necessary to control hæmorrhages, that the massive type of visceral hæmorrhages was controlled only imperfectly, that the greatest value of the treatment lay in the prophylactic injection of serum before operative procedures were practised. In sporadic hæmophilia and acute purpura, on the other hand, the results were permanent, definite cures usually being obtained. In chronic purpura and pernicious anæmia the effect of injections was only transitory. Salts of calcium have been used as a means of increasing the coagulability of the blood since the work of Arthus and Pages. Wright met with almost uniform success in the treatment of nine hæmophilic families through the use of calcium salts, fibrin ferment, and carbon dioxide. Robertson, Illman, and Duncan, using calcium salts in other hæmorrhagic conditions, were unable to confirm Wright's results either with reference to the shortening of the coagulation time or controlling of hæmorrhage.
- 4. Obliterating Endarteritis.—Painter states that the problem of ameliorating the sufferings of bad cases of erythromelalgia is a difficult one. Elevation of the limb and the enforcement of absolute rest to the part seem to offer the greatest chance of relief. The question of when surgical interference should be practised is one of great difficulty. It seems impossible to determine when an obliteration of vessels, such as is known to take place in erythromelalgia, will have attained sufficient severity to demand amputation. Certainly obliteration of pulsation in the dorsalis pedis vessels is not a condition which indicates it. The sufferings of these patients occasionally justify such radical measures. Ultraconservatism should characterize the treatment of these cases by the surgeon, but he should be ready to interfere when the conditions demand it. In an-

gina cruris, where static disturbances exist, they should be alleviated, but the most benefit will follow vibratory massage and all those measures which are designed to overcome the hunger of the muscles for an adequate blood supply. The gangrenous conditions which result from extreme degrees of arteriosclerosis, whether senile or syphilitic, must be managed by following out all procedures which lessen resistance to the flow of blood, and having determined the limits of viability of tissue supplied by the obliterated artery, the surgeon must remove these parts, where the circumstances call for it, and the patient is in a proper state to withstand it.

3. Imperforation of the Lachrymonasal Duct in the New Born, and Its Clinical Manifestations. -Zentmayer observes that to those familiar with the occurrence of the affection, its diagnosis presents no difficulties; but to the general practitioner, alert to possible occurrence of gonococcal conjunctivitis, the presence of a white secretion in the eye, just after birth, is a disturbing symptom. The absence of inflammatory phenomena, with puffiness of the lids, the benignity of the course, the usual monolateral development, and the scantiness of the discharge, should ease his mind, and if it does not, a microscopical examination of the discharge would. Varied opinions are held concerning the proper management of these cases. Some surgeons, be-lieving that as the condition is one which, in the vast majority of instances, will correct itself in time, presumably without exciting any secondary disturbance, advise a simple collyrium, the use of solutions of silver, of pressure, and massage, until Nature has asserted herself, or for several months before employing operative procedures, others employ probing or syringing. The author favors probing, which is done under different circumstances from those in lachrymal obstruction in the adult. As a rule, no resistance is met with, and the probe readily follows the natural passage, which is inclined much more backward than it is in the adult, a probe making an angle of about 45 degrees with the forchead when

5. Typhoid Fever.--Harbin has treated 148 patients with therapeutic fasting. He comes to the conclusion that the food factor in the treatment of

typhoid fever is the most important practical question to be solved. Toxemia is more marked in cases having gastrointestinal disturbances, and clinical evidences warrant liberal feeding only in a few cases. The chief source of development of the Bacillus typhosus is found in the intestinal canal and the lymphopoietic system. The aim should be to nourish the patient without increasing saprophytosis, and the battleground of treatment lies in the gastrointestinal tract. A greater danger exists from a toxic paralysis of nutritive activity of the cell than from inanition. Any vital organs containing pathognomonic lesion of an infectious disease demand absolute rest. The excessive nitrogenous waste in typhoid fever is not due to the endotoxines of the typhoid bacillus, but probably mixed infections, and the specific typhoid toxine is not necessarily accompanied by high temperatures. Emaciation occurs independently of the amount of food taken and results more rapidly from toxemia than from any lack of nourishment. The patient's life depends on attempting to maintain a normal nitrogen metabolism. The proper food management will shield a patient from the usual dangers of typhoid fever. Sthenic cases furnish the more dangerous types of the disease, and these are more amenable to therapeutic fasting, while ambulatory cases are not less prone to intestinal complications than others. A greater danger arises from septic conditions set up by a hæmorrhage than the mere loss of blood entails. Symptoms are no guides as to the presence of intestinal lesions, consequently patients require more or less routine feeding. Abortive cases show a greater tendency to relapse. Tympanites furnishes an increased area for absorption, and is provoked by any surplus of food, which increases peristalsis. Scientific data prove that clinical diagnoses may be made with a reasonable degree of accuracy. Therapeutic fasting allows an uncomplicated typhoid infection to pursue a normally mild course without any mixed infection, by reducing the bacterial content of the intestines. This was applied only to the severe cases. Fasting will enhance the effect of hydrotherapy, and frequently render the use of antipyretic measures unnecessary. Gelatin is a valuable food in that it lessens the nitrogenous waste and prevents hæmorrhage. The low mortality in this series of cases was greatly due to the elimination of relapses and complications among the mild or abortive cases by restricted feeding and lessening the dangers in sthenic patients by fasting. In this report forty-five consecutive cases occurred without a death. Of the 144 whites, five, or 3.4 per cent., died, and the low mortality, 4.7 per cent., of all cases was ascribed to the dietetic management, though many of the cases had very inefficient nursing.

6. Migraine of Occupation.-Walton remarks that migraine is an occupation neurosis resulting, in individuals of neurotic inheritance, from overuse, or use under the handicap of refractive error, of the parts concerned in vision. It involves, like other occupation neuroses, disturbance of (1) sensory cerebral centres (those of vision in the occipital region); (2) motor cerebral centres (centres of divergence and convergence in the frontal lobe); and, (3) certain muscles (particularly the intrinsic and extrinsic

muscles of the globe, the corrugator supercilii and the occipitofrontalis, and also the muscles which steady the head). The pain of migraine is not necessarily intracranial, but is localized, in part at least, in the region of the muscles concerned, directly or

indirectly, in vision.

7. Eyes in Pregnancy.-Wood states that apart from the various nervous symptoms incidental to pregnancy, which often affect the eye functions, there are four serious ocular manifestations seen more or less frequently during pregnancy or after parturition. These are: (1) The so called uræmic blindness, which is usually seen in connection with eclampsia. (2) What has always been termed the albuminuric retinitis of pregnancy. These are the most common complications. Rarer forms are (3) loss of central or peripheral vision, due, so far as symptoms point, to a retrobulbar neuritis, and (4), a form of neuroretinitis, not essentially suggestive of the albuminuric type, but showing numerous retinal exudates and hæmorrhages. The clinical symptoms of these conditions are reviewed, and the classes are studied from the standpoint of recent pathological investigations in the obstetrical field. There is, in view of these investigations, doubt as to whether the term uræmic should be applied to the blindness occurring in connection with puerperal eclampsia. The same is true regarding the renal origin of what is termed the albuminuric retinitis of pregnancy. There is good reason to think that both the renal and ocular complications are manifestations of the same process-a toxæmia. The third and fourth varieties of ocular complications of pregnancy are also, doubtless, the results of pregnancy toxæmia, a toxic neuritis or toxic thrombosis probably being the active factor in causation,

9. Hæmorrhage into the Ventricles.-Allen reports ten such cases. Four patients had convulsions, rupture of the hæmorrhage into the ventricles and involvement of the optic thalamus. One patient had rigidity, rupture of the hæmorrhage into the ventricles and involvement of the optic thalamus. One patient had convulsions, no hæmorrhagic rupture into the ventricles, but an involvement of the cortex and subcortical white matter of a sensory region. Three patients had no convulsions and no optic thalamus involvement. Two of these had ventricular inundation; one of them had not. One patient had no convulsion and had optic thalamus involvement. His conclusions are: I. Ventricular inundation in cerebral hæmorrhage has no ætiological bearing on the convulsions or rigidity. 2. Purely tentatively and basing his opinion on the findings in ten cases, he concludes that convulsions and rigidity in apoplectiform hemiplegia are frequently due to an involvement of the optic thalamus, or the corticothalamic sensory fibres, with the necessary proviso that enough of the posterior limb of the internal capsule remain uninjured to convey the motor impulses. 3. Convulsions and rigidity in apoplectiform hemiplegia may be caused by a sudden or rapid increase in intracranial pressure due to cerebral hæmorrhage, even though the optic thalamus and the corticothalamic sensory fibres are uninvolved. In such a case there must be a sufficient

preservation of the motor part of the internal capsule for the transmission of impulses to the parts concerned. 4. It is altogether unlikely that pressure or chemical change acting on the motor axons of the centrum or internal capsule-these axons having been severed from their perikaryons by the hæmorrhagic process-could exert a stimulating action sufficient to cause convulsions or rigidity.

Note on Deutschmann's Serum against Infectious Diseases,
A New and Efficient Method of Room Disinfection.
Preliminary Announcement. By W. B. McLaughlin.

4. Note on Deutschmann's Serum against Infectious Diseases.—Caravia states that Professor R. Deutschmann in his endeavors to evolve a preparation against infectious conditions of the eye, noticed that if horses were fed with increasing doses of sterile yeast for a definite length of time, they acquired a greater power of resistance against microbic infections. With the object of utilizing this fact in the treatment of infectious diseases, Deutschmann was led to draw from the blood of animals thus treated a serum, according to the usual technique. Thus far the results obtained have encouraged him and others, who have been using the serum for the last year or so, in the belief that a valuable weapon has been added to the armamentarium of physicians and surgeons in their combat against local or constitutional infectious diseases. Deutschmann's serum is not a bactericide or an antitoxine, it is a serum neutralizing germs of all kinds; not germs of one kind only. Its action is due to the introduction into the circulation of yeast fed animals of an as yet unknown substance, which seems to be an ultimate result of a series of chemical reactions set up in their digestive apparatus. As long as the animal's health is normal, this unknown substance remains in the circulation unchanged and unutilized. If, however, the animal is exposed to a bacterial infection, the cells of the yeast fed animals will take up this unknown chemical substance, which, by imparting new energy, increases their resistance to the bacterial invasion of the organism. The same action takes place if a serum from yeast fed animals is injected into a patient suffering from microbic infection. The strengthening of the cells and their increased resistance put the infected body on the same plane as that of a healthy one, able to defend itself against invading microorganisms. The dose varies according to the age of the patient and severity of the infection, from 0.75 to 1.0 c.c. in young people. to from 2 to 4 c.c. in adults. The initial dose should be the larger one. One, or at the maximum two days later the injection in smaller doses must be repeated if there is not an initial fall in temperature. In chronic cases one injection of 0.5 to 4.0 c.c. is

given and if necessary repeated, according to the results obtained, two or three times a week, provided no special idiosyncrasy against the serum exists. In such cases treatment must be stopped, to be started again a few days later. The injection is usually given into the cellular tissue. When injected into the muscular tissues preference should be given to the pectoral or abdominal muscles. The serum may be given by the rectum instead of subcutaneously. As the small amount of liquid used may be retained in ordinary syringes, Deutschmann advises the attachment to a Pravaz syringe of an olive pointed capillary catheter, for the rectal injection; in such cases the dose must be doubled. Judging from the results already obtained, it can be said that in Deutschmann's serum we have a valuable therapeutic agent which is destined in the course of time to take a prominent place in the every day practice of those who object to the depresing effects of other

5. A New and Efficient Method of Room Disinfection.-McLaughlin describes the methods of disinfecting dwellings. There are at present three which are used: I. What is known as the "Maine Method," i. e., obtaining formaldehyde gas by mixing 300 c.c. of 40 per cent. solution of formaldehyde and 150 grammes of potassium permanganate for each 1,000 cubic feet to be disinfected. The most prominent exponent of this method is the United States Public Health and Marine Hospital Service. 2. The "Walker Method," which consists in dissolving 20 to 25 pounds of commercial aluminum sulphate in 5 gallons of water, adding to this mixture 15 gallons of 40 per cent. solution of formaldehyde, and liberating formaldehyde gas by mixing 8 ounces of this mixture and I pound of unslaked lime for each 1,000 cubic feet to be disinfected. The most prominent exponent of this method is the New York Health Department. 3. The "Stewart Method," which consists in thoroughly spraying the walls, furniture, and floor of the room with a 20 per cent. solution of formaldehyde gas, and then spraying the mattresses, laying one on top of the other, and then the pillows, bedding, etc. The most prominent exponent of this method is the Philadelphia Health Department. In the first two methods (the Maine and the Walker methods), penetration to any extent is not alleged, and it is the custom both of the Marine Hospital Service and of the New York Health Department to disinfect articles such as bedding, clothing, etc., in the steam autoclave. But in the Stewart method it is stated that the disinfection is sufficiently perfect to render steam sterilization in the autoclave unnecessary. Dr. McLaughlin found that if the gas formaldehyde is mixed with vapor of carbolic acid, the tendency to polymerization does not seem to exist, and that the formaldehyde penetrates as one would expect, i. e., obeys the ordinary law of diffusion of gases. The mixture which he has used is 75 per cent. of a 40 per cent. solution of formaldehyde and 25 per cent. of carbolic acid. He uses 8 ounces of this mixture to 1,000 cubic feet of air space, and allows the room to remain closed twelve hours. He has used a retort to volatilize the mixture, but, as a matter of convenience, usually saturated a sheet and hung it up in the room to be disinfected (an ordinary sheet will hold about 6 ounces of the mixture). He was very successful with his tests.

The Value of Bilateral Ureterostomy (Shortcircuiting of the Urine) in Advanced Cancer of the Bladder or Prostate, and as an Adjunct to the Removal of the Bladder in Uncontrollable Localized Disease,

By E. H. Fenwick.

1. Disappearance of Pain.—Bennett's conclusions regarding the spontaneous modification or disappearance of pain are as follows: 1. No accurate estimate of the behavior of pain is possible in the absence of a careful study of the temperature of the patient. 2. Sudden or rapid disappearance of pain should never be accepted without reserve on its own account as a sign of improvement. 3. Sudden disappearance or rapid diminution of pain, unless it be coincident with proportionate improvement in the associated symptoms, is often a sign of impending disaster, and not an indication of recovery.

3. Abdominal Hysterectomy for Fibroids .-Bland-Sutton states that the removal of the uterus by the abdominal route, when it is occupied by troublesome fibroids, has become a fairly safe procedure. Yet, like all other major surgical operations, it is attended by certain special risks. One of these is the liability of injuring one or both ureters. Unpleasant sequelæ, and especially that form of sudden death during convalescence which is usually attributed to pulmonary embolism, are more frequent in the practice of those who habitually operate slowly. Another risk is that of the development of cancer in the stump left after subtotal hysterectomy. Such cases fall into four groups: I. The disease was present in the neck of the uterus at the time of the primary operation, but was overlooked. 2. Cancer attacked the cervical stump subsequent to subtotal hysterectomy. 3. The fibroid which necessitated the hysterectomy was really a sarcomatous tumor of the uterus. 4. The suspected growth on the cervix is not malignant, but a granuloma. In performing subtotal hysterectomy for fibroids in women of fifty years and upward, the surgeon should have the uterus opened immediately after its removal and assure himself that the endometrium is free from cancer. The most insidious danger is the occurrence of an encapsuled sarcoma in the guise of an innocent fibroid; fortunately, it is rare. The immediate results of preserving at least

one healthy ovary in this operation are admirable, especially in women under forty years of age, for the retention of an ovary is of striking value in warding off the severity of an artificial menopause. Such a belated ovary remains active and discharges ova if the woman is under forty years of age; above that age it atrophies and menopause symptoms ensue. In a very large number of instances fibroids and pregnancy coexist and no harm ensues, for, though the tumor occupies the pelvis in the early stages, it is so much "part and parcel" of the uterus that as the enlarging organ rises up out of the pelvis it carries the fibroid with it. Ovarian

tumors give more trouble to parturient women than

fibroids, but the latter are far more lethal, as they

frequently destroy pregnant women by sepsis. 4. Rickets.—Findlay has studied the ætiology of rickets and has arrived at the following conclusions: 1. Not one of the many theories which have been elaborated to explain the cause of rickets has been universally accepted, and they all lack, not only from the clinical but also from the experimental aspect, unequivocal proof. 2. It is some error in feeding which, in England and America, is commonly believed to bring about the disease, but it is doubtful, however, if feeding plays any important part in the ætiology of rickets. Experimentally it cannot be caused by improper feeding. 3. By confining young dogs and depriving them of exercise rickets has invariably been induced, as in experiments detailed by the writer, and that although their diet was beyond suspicion, the air which they breathed pure, and their kennels were kept scrupulously clean, whereas control animals allowed exercise, but otherwise similarly treated, did not become affected. 4. Examination of the conditions under which rachitic children are reared reveals one constant and invariable factor in their lives, namely, confinement. Alike, then, on clinical and experimental grounds, the writer concludes that confinement, with consequent lack of exercise, is the main factor in causing the disease. It is possible that there may be a toxine responsible for the immediate results, but without lack of exercise this toxine will not produce any injurious effects.

8. Bilateral Ureterostomy.—Fenwick advances the following propositions: 1. What can be done for uncontrollable and luxuriant benign villous growth of the bladder, in which the patient suffers from exhausting hæmorrhage or uncontrollable pain, or is commencing to suffer from ascending septic changes along the ureters? In such a case bilateral nephrostomy, or, better still, ureterostomy, should be performed, and a fortnight later the bladder should be removed, if the patient's physical condition and future seem to admit of this mutilation. 2. If the bladder is affected by interstitial cancer, which has so invaded the surrounding areas so that no chance remains of removing the organ, then bilateral ureterostomy is wiser, for this will relieve the patient of the agony of urination. 3. If malignant disease is detected early, as it can be by the cystoscope, it is wiser to perform double ureterostomy; and if the physical and renal condition of the patient permit, let the bladder, with or without the prostate and seminal vesicles, be entirely ablated.

 By O. J. CURRIE.
 Matering Notes,
 By C. T. W. Hirsch.

1. Errors of Metabolism .- Garrod, in the first of his Croonian lectures, discusses our present conception of metabolism. Actual derangements of the metabolic processes follow almost any deviations from the normal health. In addition there is a group of maladies in which metabolic disturbances are by far the most conspicuous features, though the structural changes behind them are scanty or inappreciable. Of such "diseases of metabolism," diabetes, gout, and obesity are the most important. At first sight there appears to be little in common between inborn derangements of function and structural defects, but the difference is rather apparent than real. Very slight structural changes may lead to profound functional derangements, as witness the effects of atrophy of the thyreoid gland. So that under each chemical abnormality or "sport" may well exist some abnormality of structure so slight that it has hitherto escaped detection. Among the complex metabolic processes of which the human body is the seat, there is room for an almost countless variety of such "sports," but the examples that can be adduced are very few in number. The only known anomalies that can be assigned to this class are albinism, alkaptonuria, cystinuria, and pentosuria. That albinism is congenital and persists through life is self evident. The lifelong persistence of alkaptonuria is equally well established, but it may also occur as a temporary phenomenon. Its remarkable staining property allows of its recognition at the very beginning of life. The evidence of the congenital occurrence of cystinuria is much more difficult to obtain. There is abundant evidence that it is present in early childhood, and that it may persist for many years. No direct evidence of the congenital occurrence of pentosuria is as yet forthcoming; it is included in this group on other grounds. Cystinuria is probably the least rare of these four conditions, and it is the only one that can be classed as distinctly harmful, by means of the formation of calculi, due to the insolubility of cystin in urine. All of these abnormalities have one feature in common—the liability to occur in several members of a family, most often in collaterals of the same generation. In albinism there is a defect of substances which are normal constituents of certain specialized tissues, and which serve purposes of much utility to the organism. The essential phenomenon is the absence of the pigments of the melanin group. Three explanations suggest themselves. The cells which usually contain pigment may fail to take up melanins formed

elsewhere. The albino may have an unusual power of destroying these pigments. Or, finally, he may fail to form them.

2. Operation for Heart Disease.-Morison in 1897 suggested the severing of pericardial adhesions for the relief of cor bovinum. Since then, however, he has grown convinced that it was less the tethering of the heart than its bulk and force of systole which were the determining factors in the situation, and that operation to afford room adequate for the free action of the enlarged organ was the primary consideration whether the organ itself were tethered or not. It is often observed that a large muscular heart, usually associated with valvular disease and without extraneous adhesion, will succumb to the mechanical difficulty while possessing apparently an amount of wholesome muscle which should have been adequate to contend with the obstacle in the circulation for a much longer period had it not been exhausted by some other cause. Given such a large heart, powerfully pulsating against hard and resistant structures, what more natural than that the striking and indirectly struck organ should from time to time develop a condition of excitation or erythism in excess of what is normal to it, and that such erythism should be associated with increased systolic pressure, augmented by mental causes due to subjective discomfort in various degree, from uneasiness to pain. We may conclude that one cause, at least contributory, to attacks of angina in aortic valvular disease with hypertrophied heart is direct stimulation of the organ by systolic impact against costal resistance, and this may also be regarded as a cause of the premature failure of the hypertrophied heart so frequently observed in practice. The writer reports the case of a young man, aged nineteen years, who had suffered from aortic valvular disease for a number of years. The heart being greatly enlarged, it was determined to afford it more room to act in while its power was still good, by securing free space for cardiac systole without the incarcerating barrier of hard rib, in the area of thoracic concussion. A V shaped incision, with its descending limb in the centre of the sternum, commenced at the level of the sternal attachment of the third rib. Sweeping round at the level of the seventh rib, the ascending limb of the incision was carried to a point corresponding with its commencement. large flap was thus secured and raised, consisting of superficial textures and muscle down to the ribs. This was turned back and spread between warm, moist towels. The fourth and fifth intercostal spaces were next cleared down to pleura, and the fifth rib, covered by its periosteum and perichondrium, carefully separated from the underlying pleura, and four and a half inches of its length, from the sternum outwards, were removed in three pieces. The sixth rib was similarly cleared, and five and a half inches of it were removed in one piece, its greater arching allowing more easy detachment without injury to pleura. The internal mammary artery required ligature. A small puncture was made in the pleura, while the last portion of the fifth rib was being removed, air being aspirated through it during respiration. The puncture was stitched,

but was not rendered quite airtight thereby. The raised flap was then replaced and accurately applied by alternate gut and horsehair sutures, a drainage tube being inserted at the lower left hand angle of the wound. The patient took the chloroform well. The effect of the operation objectively and subjectively was very satisfactory. The pulsation became less forcible and the blood pressure was lowered. The anginoid pain previously complained of was greatly diminished in amount and intensity.

I. Emergency Treatment of Acute Osteomyelitis of Ado-By HARDOUIN.

The Purgative Properties of Phenolphthaleine, By BERTHOUMEAU and DAGUIN.

3. Treatment of Burns with a Dressing of Horse Serum,
By R. ROMME.

 Acute Osteomyelitis of Adolescents.—Hardouin asserts that the acute osteomyelitis of adolescents is an infectious intraosseous lesion, the treatment for which may be briefly summed up thus:

Trephine always early and freely.

2. Purgative Properties of Phenolphthaleine. -Berthoumeau and Daguin state that phenolphthaleine augments by direct contact the contractility of the intestine and its secretion. A dose of from fifty to eighty centigrammes causes a purgative, and one of twenty-five to thirty centigrammes a laxative effect on an adult without producing any abdominal pain. In children, in doses according to age, it is a satisfactory and inoffensive evacuant. With respect to its action on the intestine it does not appear to provoke notable modifications of the diverse functions.

I. Trade and Dwellings of Washerwomen and their Relations to Tuberculosis, By Professor L. LANDOUZY.

Departmental Disinfection, By Professor J. COURMONT. Physical Properties and Method of Application on High Frequency Currents, By A. ZIMMERN.

Trade and Dwellings of Washerwomen with Reference to Tuberculosis.-Landouzy says that in the Laennec hospital the frequency of tuberculous infection is twice as great among washerwomen as in any other trade, and that the mortality therefrom is twice as great among them as among workers at any other trade in which the cosmic and economic conditions are the same, such as salaries and hours of work. Hence, he concludes that the trade of washerwoman favors tuberculous infection. When these women have become tuberculous they infect their dwellings and create new foci for the dissemination of the disease.

- 1. Complication of Myeloid Leuchæmia.-Frugoni's special complication of myeloid leuchæmia consists of the formation of an intramuscular hæmatoma caused by intramuscular myeloma which he defines as an intramuscular myeloid metastasis. He sums up his observations in the following conclusions: I. In the course of an advanced myeloid leuchæmia a thick intramuscular hæmatoma may appear spontaneously. 2. Both in regard to the way and manner of its appearance and in regard to its course the hæmatoma presents peculiar clinical characteristics. It is a very rare phenomenon and increases the unfavorable nature of the prognosis. 3. The hæmatoma is in no way dependent upon a preexisting, concomitant hæmorrhagic diathesis, the usual symptomatology of which is wanting, but is of local origin. 4. The origin of the hæmatoma is to be ascribed chiefly to the preexistence of an intramuscular myeloma, which together with the special vascular changes furnishes the predisposing anatomical substratum whence the complication is called forth by the action of the numerous actuating causes. 5. The condition of an intramuscular myeloid metastasis is exceedingly rare, the author has found no other example in literature, and seems to support the neoplastic theory of the leuchæmias suggested by Banti.
- 2. Laryngeal Disturbances in Beriberi.—Kanasugi reports seven cases of beriberi with paralyses of the vocal cords or œdema of the larynx, and illustrates his article with drawings that portray the laryngeal condition in each case.
- 3. A Microsporon Epidemic.-Glaser gives the recommendations of His at the dermatological Congress at Bonn, viz:—1. Centralized treatment in epidemics of microsporia. 2. Regular investigation of all classes in an infected school. 3. All boys to have their hair cut short in order that the examination of their heads may be facilitated. 4. X ray treatment of the diseased skin of the head. 5. All diseased children to wear a proper dressing on the head.
- Chronic Diphtheroids in the Throat.—Gabriel reports the case of a woman, twenty-two years of age, who recovered from an attack of diphtheria, but more than a year later continued to complain of her throat and to have occasional attacks of fever. She was also known to have communicated diphtheria to two other persons more than a year after her recovery. Smears taken from her fauces and tonsils showed the abundant presence of Loeffler's bacilli which presented all their characteristics and were virulent for animals.

- 1. Paratyphus and Melæna of the Newly Born.-Nauwerck and Flinzer report the conditions found at autopsy in a child that died thirtysix hours after birth, together with the findings from cultures, agglutination tests, and experiments on animals. The principal lesions found were multiple circumscribed areas of necrosis of the stomach, associated with inflammation and ulceration, slight swelling of the spleen, otitis, cholecystitis, and a hæmorrhagic diathesis. The tests seemed to show that the cause was a primary blood infection with the Bacillus paratyphosus B.
- 2. Action of Old Tuberculin on Nontuberculous Men .- Hamburger asserts that Koch's old tuberculin exhibits a demonstrable toxic action only in the tissues of men who have either active or latent tuberculosis, and that it is apparently nonpoisonous to those who have no tuberculosis.
- 6. Graser's Operation for Large Umbilical and Ventral Hernias.-Port has performed this operation, which was brought forward by Graser in 1906, in seven cases, three of them over a year ago. In these three patients the abdominal wall continues to be firm, and he strongly recommends the operation for all large hernias of this nature
- 7. Stomach Operated on Four Times as the Result of a Mistake in Diagnosis.—Eschbaum reports a curious case in which a man, thirty-seven years of age, had suffered for four years from sudden attacks of severe pain in the region of the stomach, associated with vomiting of sour tasting material. The symptoms were so indicative of stenosis of the pylorus that on four separate occasions the pylorus had been investigated surgically without benefit. Finally the diagnosis was determined to be "gastric crises in tabes dorsalis.
- 8. Traumatism and Appendicitis.-Vogel reports a case which strongly supports the view that appendicitis is caused by traumatism. A man heard a wagon coming behind him, turned sharply, and at the same time sprang to one side. He was immediately seized with severe pain in the region of the cœcum, was operated upon within a short time, and the appendix found to be torn in two with the fragments widely separated.

9. Fibromatous Thickening of the Tendo Achillis. Schwarz reports a case in which a fibroma in which the fibres were loosely arranged was removed from the tendo Achillis of a man, forty-one years of age. As regards the ætiology, Vogel is uncertain whether the growth was due to rheumatism, to an accidental injury of the tendon, or to a combination of both these factors. No salts of uric acid could be found in the tumor.

10. Inflammation of Meckel's Diverticulum .-Gebele reports the case of a woman, forty-eight years of age, who was operated upon for perforation of the appendix vermiformis and diffuse suppurative peritonitis, and found to have instead a purulent inflammation of the Meckel's diverticulum, which had ruptured.

 23. Modern Medicine and Surgery in the Orient,
 P. J. F. Modern

By J. E. MEARS. 4. Treatment of Perforative Peritonitis .-Murphy considers three forms of peritonitis, chemical, mechanical, and bacterial. The first apparently has no microbes. The sources of infection in more than 90 per cent. of the cases are the appendix and the pylorus. Early in the disease there is acceleration of absorption, later this process goes on more slowly. The term free peritonitis should be used for the diffuse form, and circumscribed for the encapsulated form. The modern treatment of general septic peritonitis has greatly reduced the mortality. The Lewler position should be used both before and after operation. The relief of pus tension is the first surgical step in retarding absorp-

tion in all acute infections. Drainage should be initiated as quickly as possible. Proctoclysis carefully administered is very important. Opium and coal tar products should not be given before or after operation. Ileus is a frequent and annoying symptom. There should be early diagnosis and early intervention, anæsthesia should be brief, and there should be the slightest possible trauma to the peritonæum. The blood pressure should be restored, sepsis eliminated, and absorption inhibited by position.

- 5. Late Results after Operations for Benign Diseases of the Stomach and Duodenum.-Moynihan submits the following points: I. The operative treatment of stomach disorders should be confined to those cases in which an organic lesion is present. 2. In acute perforating ulcer, the perforation should be closed or the ulcer excised. This is all important if the ulcer is on the lesser curvature. Gastroenterostomy should be performed if the ulcer is prepyloric, pyloric, or duodenal.. 3. When a nonmalignant lesion is discovered, the proper treatment will depend upon its position in the stomach. Excision should be performed if the ulcer causes no obstruction to the onward passage of food. 4. In addition to gastroenterostomy, an ulcer should be infolded when possible. 5. The posterior no loop form of gastroenterostomy with almost vertical application of the bowel to the stomach is the most satisfactory method. 6. Regurgitant vomiting follows the loop operation whether anterior or posterior, but this may be relieved by enteroanastomosis. The vomiting of bile may be relieved by lavage, and after a time may disappear entirely. 7. In hour glass stomach the two lesions, one in the body of the stomach and the other at the pylorus, may necessitate a double operation.
- · 7. Endresults Following Operations for Benign Diseases of the Stomach and Duodenum .-Deaver analyzes his work in this field, and draws the following conclusions, influenced by the immediate dangers in the different varieties of operation: 1. The operation of choice should always be performed when feasible, otherwise the operation of necessity must be performed. 2. All cases of stenosis of the pylorus, whether due to neoplasm, cicatricial contraction, hyperplasia, or pylorospasm, should be subjected to operation, preferably to posterior gastrojejunostomy. 3. All cases of ulcer of the stomach which do not promptly respond to medical treatment, and the various sequels of this disease, should be treated by operation. 4. All cases of ulcer of the duodenum which do not promptly respond to medical treatment should be subjected to operation. 5. The author's preference in performing gastroenterostomy is by the posterior gastrojejunostomy, no loop, clamp route.

 By P. G. Heinemann.

 The Serum Treatment of Cerebrospinal Meningitis,

 By L. E. La Fétra.
 - Symposium on Rheumatism in Children, PHILADELPHIA PÆDIATRIC SOCIETY.
- 1. Intestinal Intoxication in Infants.--Kimball emphasizes the greater importance of this con-

dition in children than in adults. Many lives are sacrificed on account of ignorance upon this subject. Many supposed cases of meningitis, cerebral hæmorrhage, and other grave central conditions are due to intestinal reflexes alone. The author does not include cases which are accompanied by diarrhœa, but only those in which the poison is locked up within the bowel, with rapid absorption. Only heroic measures in such cases will cause the bowel to empty itself. The treatment for these cases should consist mainly of cathartics, and of these calomel and castor oil in large, even heroic doses, are to be preferred. Pure castor oil may be given every few hours for several days without fear. Enteroclysis should be used in these cases if the temperature is high, and if there are bloody stools and tenesmus. In delicate babies it is a dangerous procedure. In severe toxic cases irrigation should supplement cathartics, and the bowel should be thoroughly washed out. Concerning food, fresh milk should not be given until all traces of infection have disappeared. The author prefers a diet containing equal parts of animal broth and cereal decoction; in other words, chicken, mutton, or veal broth, with equal parts of granum, barley, or arrowroot gruel. The last is to be reserved for cases of diarrhœa. In acute cases give only pure water, or albumin water containing also a little brandy.

2. Some Advances in Infant Feeding.-Lamb summarizes his paper as follows: 1. The most important thing in infant feeding is to know the amount taken in twenty-four hours. The only way to do it is to calculate energy quotients. 2. The percentage method is uncertain and complicated. 3. The quantity of food and not the percentage is desirable. 4. Overfeeding is the commonest cause of nutritional disturbance, and is a clinical entity. 5. Fat in cow's milk is to be feared. 6. Fat causes constipation, proteids do not. 7. Curds in stools are not proteid, but calcium soaps, fatty acids, or fats. 8. Casein is not difficult to digest, does not cause digestive disturbance, nor undergo putrefaction in the intestine. 9. The new born infant can digest starch. 10. Dextrins and starches are valuable additions to milk feeding. 11. The volume of a child's food should depend on its weight and should never exceed 36 to 38 ounces. 12. The interval between feedings should never be less than three hours, and after the third month of life should be four hours.

3. Sanitary Milk .- Heinemann repeats that the sterilization of milk with destruction of its harmful bacteria is not sterilization in the modern bacteriological sense. The disadvantages of treating milk by heat after pasteurization, from a bacteriological point of view, are more pronounced than they are after sterilization. Pasteurized milk is not fit for consumption after twenty-four hours. Pasteurization does kill the pathogenic bacteria. Clean milk may be and has been produced, which will remain sweet for two weeks or even longer. The great trouble is that it is very expensive to produce sanitary milk, and the price must be raised if it is to become a profitable business. Model dairies must have competent, that is, educated, managers. The public at large is urged to take greater interest in this question.

THE JOURNAL OF NERVOUS AND MENTAL DISEASE $July,\ 1908.$

I. Disease of the Primary Motor Neurones Causing the Clinical Picture of Acute Anterior Poliomyelitis: the Result of Poisoning by Potassium Cyanide.

By JOSEPH COLLINS and HARRISON S. MARILAND.

2. The Significance of Phrictopathic Sensation,

3. Tumor of the Frontal Lobes with Symptoms Simulating Paresis,

By F. X. Dercum.

1. Toxic Effects of Potassium Cyanide upon the Peripheral Motor Neurones.—Collins and Martland report such a case. The patient, an Italian, thirty - eight years old, was admitted to the City Hospital, December 3, 1906. Since coming to this country, in 1904, he had been working as a silver polisher in a hotel. The method of keeping silver bright in such establishments is to drop it into a solution of potassium cyanide and then dry it. He says that his hands and forearms were in such solution so much of the time that they took on a deep brownish red color, and he frequently complained of a distressing itching sensation in them. In addition to this, the finger nails were quite black. He does not know how strong the solution of potassium cyanide was that he used, but he says that he had to be careful to keep his hands away from his nose or his mouth, for otherwise he would get very dizzy. On the seventh of September, 1906, he was seized with diarrhœa, which soon became very severe, the passages containing large amounts of mucus, but no blood. The following day he complained of severe headache, of pain and stiffness in the back of the neck, and of feeling ill. He was then taken to a hospital, and it is said that for a few days he was mildly delirious and had such meningeal symptoms as stiffness of the neck, retraction of the head, and sensitiveness on being handled. These symptoms continued for four or five days. there developed a sensation of stiffness of both ankles and severe pain in the legs below the knees. Within forty-eight hours his legs and arms were so weak that he could scarcely move them, and from that time he was unable to stand or walk. About this time he had retention of urine and had to be catheterized for more than a week. After that he had difficulty in expelling the urine, but he got on without having a catheter passed. At this time he did not complain of pain or paræsthesia, the symptoms were entirely of the motor apparatus, nor were there any trophic symptoms apparently. His best recollection concerning the atrophy of the muscles, which was so conspicuous on his entrance into the City Hospital, was that it was first noticed about eight weeks after the onset of his disease. The trapezii were involved to a slight extent. The supraspinati and infraspinati muscles, the serratus magnus, the deltoids, the biceps to a considerable degree, and the triceps were conspicuously atrophied. The plantars and the extensors of the forearm were also very much shrunken. In the lower extremities the muscles chiefly involved were the anterior tibial group and the posterior calf muscles, the vasti and quadriceps. For about six months there seemed to be no indication of recovery. Then gradually the atrophied and paralyzed muscles began to display functional capacity. From the experimental work which

the authors have undertaken to show the effects of potassium cyanide upon the peripheral motor neurones, they are led to the belief that the entire motor neurone is affected, the neuraxone, however, more than the cell body, but the participation of the cell body in the destructive process is fairly certain, and this participation accounts for the occurrence of spinal cord symptoms in our patient. That the atrophy, however, that is, the degeneration in the muscles, is not primarily dependent upon spinal cord lesion, is best testified to by the distribution of the atrophy. It would have to be an extremely extensive process in the spinal cord, and such extensive lesion would cause symptoms that did not occur in this case. Moreover, the degree of recovery which has taken place indicates that the cell bodies of many of the peripheral motor neurones, which at first seemed to be very profoundly diseased because of the amount of atrophy, are in reality in possession of sufficient vitality to assist in the regeneration of the diseased neuraxons.

Proceedings of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of April 27, 1908.
The President, Dr. J. Riddle Goffe, in the Chair.
(Concluded from page 140.)

The Prevention of Fœtal Infection by the Eyes, Mouth, or Umbilicus.—Dr. J. CLIFTON EDGAR read this paper. The prevention of infection by careful cleansing of the mouth immediately after the expulsion of the head was often overlooked. Cleansing of the infant's mouth at this time was especially called for after delayed or tedious labor and in instances of gonococcus elytritis in the mother. In the former case, by reason of the prolonged labor, not only did the vaginal secretions undergo changes, but an ante partum subæration of the fœtal blood, or asphyxia neonatorum, caused attempts at respiration on the part of the fœtus within the birth canal, with a consequent aspiration of maternal secretions into its mouth and pharynx. Hence the importance of mouth cleansing. It was his belief that there was no special value in chemical antiseptics for this purpose, but the aim should be to remove the foreign substances mechanically as thoroughly and at the same time as gently as pos-Roughness and carelessness in this connection only defeated the aim by causing abrasions of the delicate buccal mucous membrane, and thus predisposing to subsequent infection. Immediately upon the expulsion of the head, and even before the evelids were cleansed, the lips and nose were wiped free from mucus and foreign substances, and then the little finger, wrapped with a piece of gauze or, better, clean old linen dipped in a boric acid solution or plain water, was passed into the child's mouth, and any accumulated mucus, blood, or meconium removed by an outward sweep of the finger in each cheek

Each evelid of the infant should be carefully

cleansed by means of a piece of old linen and sterile water or boric acid solution. A separate wipe should be used for each eye, and the lids gently washed from the nose outward. Ophthalmia neonatorum produced from seven to ten per cent. of the existing blindness to-day, and only recently Mr. Simon Snell had reported that, of 333 inmates of the Sheffield School for the Blind, 136, or 42.36 per cent., had been blinded by ophthalmia neonatorum. Among the children registered in the New York State School for the Blind during the past four years, twenty-six per cent. had their blindness assigned to ophthalmia neonatorum. The midwife was largely responsible for these amazing figures. The gonococcus was found to be the cause of the infection in sixty per cent. of the cases. If at the time of birth, and before the eyes were opened, the lids were carefully and gently cleansed from within outward with gauze or absorbent cotton moistened with sterile water, and a separate wipe was used for each eye, and if subsequently, in greasing or washing the child's body, pyogenic germs were not conveyed from the body to the eyes, ophthalmia neonatorum was reduced to a very small percentage of incidence. If this was supplemented with a drop of a solution of one of the silver salts dropped on the cornea of each eye, the vitality of the gonococci that had escaped the cleansing, and found entrance between the lids, was destroyed, and the chances of the eyes escaping infection were raised to the highest point. Which silver salt to use and in what percentage were still debatable questions. During the past few years he had done much clinical experimentation with the various preparations, and he believed that much was yet to be learned concerning their use. During this time he had experimented in institution work and in private practice with seven different silver salt solutions. lieved that a solution of silver nitrate of proper strength and correct application would guard the baby's eyes from infection.

The death of infants early in their lives, without assignable cause, should always make one suspect infection through the umbilical vessels, resulting in purulent thrombi of the intraabdominal portion of the vessels. The protection of the infant from umbilical infection demanded the following conditions: That the cord be handled only with clean hands; that sterile ligatures and scissors be used in the ligation and cutting of the cord; that the raw stump be immediately covered with a piece of sterile gauze and the infant wrapped in a sterile towel, or at least in a freshly laundried one, until such time as the third stage of labor was completed and a permanent umbilical dressing could be applied; that a lubricant, and not a tub bath, be used for the first cleansing of the child and the removal of the vernix caseosa; that subsequent cleansing of the infant should be by sponging and not tubbing, until the umbilical wound had healed; that a permanent aseptic umbilical dressing be applied at birth, which should remain if possible undisturbed, until the stump of the cord should separate. As used in the tenement house service, the umbilical dressing consisted of: 1. A flannel abdominal binder thirty inches long by six inches wide, which was intended in the average

case to surround the infant's abdomen two and a half times. 2. A gauze dressing of four folds, three inches square, with the edges turned in and split from one edge to the centre. 3. Two small safety 4. Two pieces of narrow bobbin tape. 5. A small gauze wipe for the stump. 6. A pair of blunt pointed scissors. The routine was to tie the cord with as little traumatism as possible, and after the baby had been greased with sterile lanolin and the vernix caseosa removed as thoroughly as possible, the stump of the umbilical cord was placed in the split gauze dressing and the latter folded carefully over the stump; the binder was then applied and held in place with two safety pins. Unless the binder became soiled, it was left in place until the fifth day. In a series of 1,600 infants in this hospital, including 1,000 cases in the east side tenement houses and 600 in the hospital building, treated by this method, so far as was known there had not been a single case of umbilical infection. In these 1,600 cases, the average time of separation of the umbilical

stump was on the sixth day. Dr. WILLIAM S. STONE believed that the men who devoted themselves exclusively to the practice of obstetrics could be counted upon the fingers of the two hands, and probably the supply equalled the demand; there did not seem to be any demand for more. Consultation work in obstetrics was largely emergency work and was mostly limited to the latter part of labor, or to puerperal sepsis. Consultations for the consideration of conditions occurring during labor had a limited demand. Outside of the occurrence of convulsions, it was not considered necessary to ask for a consultation. He wished to call attention to one or two points. There were a number of cases constantly occurring in New York and elsewhere in which a normal woman gave birth to an eight and a half, or nine, or ten pound baby, and died after a prolonged forceps operation, and these were the cases which every one regretted, because it could not be seen how we were going to prevent them. Three, four, or five years ago he had started a study of the relative size of the fœtal head and the pelvis, and he had learned that, either by palpation or actual measurement by the so called suprapubic pressure method, he could tell with great accuracy the relative size of the fœtal head and the pelvis. This method of determining whether or not the head could go through a given pelvis, whether he spoke of it in public or in private, had been treated with indifference by his colleagues. Since then he had limited his consideration of the subject to its actual demonstration upon a few patients. This subject he believed to be worthy of more consideration; he thoroughly believed that there was no excuse for a woman's giving birth to an eight and a half, nine, or nine and a half pound child, and the child being born dead.

Dr. RALPH H. POMERGY, of Brooklyn, said (by invitation) that the Pomeroy bags must be used with great discretion, because of their great dynamic capability; used indiscriminately they might lacerate the cervix. So long as the general practitioner expected to do obstetric work, the family would expect it to be done by the general practitioner, and if there was any fault to be found with this arrange-

ment, the fault was not with the family, but with the family doctor. The general practitioner erred in not considering his own pocketbook sufficiently, and would not call for a consultation early enough to benefit the patient. The more one contemplated the fact that writers, speakers, and teachers in obstetric work were practically, as they grew older, developing into gynæcological surgeons, the more one realized what a difficult situation the teachers occupied in this matter. With regard to expressing the placenta, personally, he favored expressing it, not after half an hour of waiting, but with the first possible reasonable contraction one could get, whether the patient was under an anæsthetic or not. Detachment of the placenta occurred, if it was detachable, with uterine contraction. In every case in which he had to invade the uterine cavity to extract the placenta, the interference with its expulsion was almost always due to retraction of the contraction ring and not to any attachment of the placenta. One of the meanest hæmorrhages met with in consultation was the concealed one, in which there were a relaxed uterus and an unexpelled placenta.

Dr. George L. Brodhead emphasized the great importance of the constant observation of these patients, the regulation of the diet, and the frequent examination of the urine, as well as insisting upon the advantages of exercise up to the very day of confinement if possible. He was sure that many cases of dystocia, due to a large fœtus, especially where the pelvis was small, could have been avoided if the patient had been instructed in regard to her diet. Dr. Norris had brought out an interesting point with regard to scopolamine. The speaker had used it many times, but the results had not been encouraging; chloral and morphine gave better results in his hands. No greater advance had been made in obstetrics than by the use of the dilating bags. The bags should be used oftener than they He agreed with Dr. Cragin that the more external examinations were made, and the less frequent the internal, fewer cases of sepsis would re-With regard to the treatment of retained membranes, for the past twelve years he had not inserted the hand into the uterus to remove them. One could not be sure that he was not introducing germs when the uterus was invaded for the removal of small pieces of membrane.

Dr. JOHN O. POLAK, of Brooklyn, said (by invitation) that he believed that not sufficient attention was given by the general practitioner to the prevention of fœtal mortality, and there was probably no class of work where the life of the individual, such as the child's life, was considered of less weight than in obstetric practice, and this was probably due to two reasons: I. The woman did not come under observation early enough, and even when she did, the practitioner was careless in controlling the child's growth. 2. There was a prejudicial influence upon the practitioner's judgment as to the best procedure in the interest of the child. Tardy management was bad. It was well to recognige malpositions early, especially the occipitoposterior positions, which were so frequently overlooked, and so jeopardized the lives of the children.

With regard to the repair of lacerated cervices,

he wished to enter a protest against the repair at the time of labor in general practitioners' hands. He had never repaired a lacerated cervix immediately after delivery except in the case of hæmorrhage. With regard to the use of ergot he had gone through the period where he had used it, discarded it, and used it again; he now used it after labor, because it retracted and contracted the uterus and so tended

to prevent septic absorption.

Dr. W. GILL WYLLE believed that a good gynæcologist should be a good obstetrician; these two could not be well separated. The most important part of a woman's life was the time when she had her first baby; after the first time labor was simplified, and he hoped to read a paper on this subject shortly. Surgical principles should be applied in obstetric work, the same as after important opera-

tions, such as hysterectomy.

Dr. A. Ernest Gallant illustrated a method he had used during the past fifteen years to keep the navel aseptic. The navel should be treated as a surgical wound was treated. With the application of the dressing he presented, there should never occur any jaundice or infection. In 1900 a series of cases were subjected to experimentation; every other case was treated with the dressing applied; the others were treated in the ordinary way. In not one of the cases treated with the dressing did any jaundice or infection occur.

Dr. J. MILTON MABBOTT emphasized the importance of always warning the woman to keep her hands away from her vulva during the first few days after delivery. He reported the case of a woman who had been under his care and who said she had examined herself within twenty-four hours after delivery to learn how different she was then from before. She was attacked with pyæmia and died as the result. He said he was strongly of the opinion that massage of the breasts in mastitis was an injurious procedure. It was not indicated except to express the milk; it was no more indicated than massage of the parotid gland was in mumps.

Dr. Norris said that one was consulted in emergency work for conditions that most often called for the rapid evacuation of the uterus; these were cases of uneffaced cervix, the lower segment of the uterus unopened, the cervix elongated, the woman comatose or eclampsic or in convulsions, etc. These were the conditions met with which required the rapid emptying of the uterus. With regard to the amount of time consumed in dilating with the Pomeroy bag, it should be borne in mind that this was a slow procedure, especially in primiparæ. After dilating the cervix to about eight cm. he introduced the Pomeroy bag, and in about thirty minutes the entire birth canal was dilated so that the child could be extracted with forceps without laceration. In the ordinary cases one, two, or three hours might be consumed in this dilatation, if it was to be a safe procedure.

Dr. Cragin said he wished to call attention to the fact that he said he advised massage of the breasts when mastitis threatened. There were many cases in which the breasts were distended, the ducts not being freely opened, in which massage would empty the breast, opening the ducts so that the discharge would be free.

Metters to the Editors.

PYLORIC INSUFFICIENCY.

NEW YORK, July 10, 1908.

To the Editors:

In the *Journal* of May 30th Dr. Mark I. Knapp complains of the fact that his works on pyloric insufficiency were not mentioned in my communication in the *Journal* of May 16th.

The fact is that the said communication was such a short one that I had no intention of going extensively into the bibliography. I mentioned Serré and Ebstein, who, according to A. Mathieu, were the first to call attention to pyloric insufficiency. In my manuscript I used the word first, but for some reason, owing probably to a printer's mistake, this word was omitted from the print. As the sentence in my article reads now, Dr. Knapp has ground for complaint. Since, however, Dr. Knapp's works on the subject have been recalled to the attention of the readers of the Journal by Dr. Knapp himself, I suppose that the wrong is thereby repaired, and the matter can be considered as settled.

E. Palier.

A MONSTROSITY.

119 EAST SEVENTY-SIXTH STREET, New York, July 14, 1908.

To the Editors:

A description of this monstrosity may be of interest. The child, female, born at term, had no parietal bones. The cranium terminated in an irregular ring formed by the frontal, temporal, and occipital bones, and from this ring protruded a mass of brain substance, covered by the membranes. This mass projected beyond the edges of the bony ring like a cap. The scalp ended at the edge of the ring, where the skin was firmly attached to the irregular edges of the bone, forming a smooth cushion. The cerebral mass protruded nearly half an inch above the top of the frontal bones, and the dura was thick and tensely drawn over the mass, so that pulsating folds were distinguishable. Pulsation could be felt all over the mass, but the slightest pressure caused the child to cry. A hæmorrhagic exudate from innumerable capillary points on the dura began a few minutes after birth and persisted until the child's death, fourteen hours later. During this time the child cried, was quiet when fed, slept, and was otherwise apparently normal. After death the cerebral mass contracted somewhat, but still formed a protrusion above the ring of bone. Delivery was uneventful. The membranes ruptured twenty-four hours before labor pains began, and labor lasted altogether less than three hours. The mother had two falls during the seventh month of pregnancy. Once she slipped off a chair, sitting down heavily, and a few days later she fell upon her abdomen. She also had several bad falls before these, once falling from a low ladder upon her hip. Her first child, now seventeen months old, is healthy.

I. L. NASCHER.

New Inventions.

A RETRACTOR FOR MINOR SURGERY. By Andrew J. Gilmour, Ph. B., M. D., New York.

This minor surgery retractor consists of a ring and a rod ending in a tenaculum. The entire length is two inches. The ring is three quarters of an inch in diameter, with a breadth of three sixteenths of an inch.

The rod, which is very delicate, projects from the side of the ring at a right angle to its tangent. Its length is one inch, but at five eighths of an inch from the ring there is a slight bend of the rod upward, so that the remaining three eighths of an inch will be parallel with any flat surface upon which the

retractor may lie. At its end the rod spreads into three tenacula; these are exceedingly sharp and small, and are designed to bury themselves well into the tissues.

These tenacula are turned downward at a right angle for one eighth of an inch, and for this distance are parallel to the perpendicular diameter of the ring. The tips are then turned inward at a little less than a right angle, and form teeth which are one sixteenth of an inch in length. The ring is to be worn on the little or ring finger, which will allow one to make traction on the wound and at the same time have the thumb and forefinger free for the use of the thumb forceps or manipulations which the exigency of the case may demand. The upward bend of the rod allows it to lie flat on the surface next to the wound. The right angle arrangement of the tenacula fits better in an incision, a great advantage over the bulging of rounded tenacula. These last two facts, combined with the small size of the instrument, give an unobstructed view of the field of operation.

The object of these retractors is to avoid the necessity of an assistant in such operations as the removal of small tumors, opening of infected hands and tendon sheaths; and also to give the greatest possible view of the limited operative field. Although of very delicate construction, they are made of hand forged steel, and by tests have been shown to stand a tension of at least twenty-five pounds.

133 EAST FIFTY-SEVENTH STREET.

Book Aotices.

(We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.)

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M. D., F. R. C. P., Consulting Physician to Gry's Hospital, etc. Eighth Edition. London: J. & A. Churchill, 1908 (through P. Blakiston's Son & Co., Philadelphia). Pp. xvi-1111. (Price, \$6.40.)

The popularity of Dr. Taylor's excellent manual

is sufficiently attested by the fact that eight editions of it have been issued in as many years. The eighth edition has been thoroughly brought into accord with the present state of our knowledge, and much new matter has been added. Necessarily the book is condensed in style; that was required to keep it within the bounds consistent with comfortable handling. The condensation, however, has not been made too pronounced.

Acute rheumatism is classed among the infectious diseases, perhaps properly, but in the paragraph devoted to its ætiology we find nothing suggestive of infection. The section on paratyphoid fever is brief but very satisfactory. The subject of typhoid fever is well handled, though, in accordance with the present British custom, precedence is given to the name "enteric fever." On page 7 the author seems to extend the meaning of the term bacteriology so as to make it cover the study of all pathogenic microorganisms, whether vegetable or animal, by a sort of metonymy which appears to us to be of doubtful propriety. His remarks on tetanus antitoxine seem to us to verge on unwarrantable skep-The term equinia is used, on sufficient authority, as a name for glanders, but the reader might have been told that it also meant horse pox. We do not find the expression cardiac arrhythmia employed anywhere in the book. Uncinariasis, too, is not mentioned, but the fact that the parasite to which it is due is distinctively American may well enough account for the omission. McBurney's point is indicated as "a point about three inches from the right anterior superior spinous process, on a line drawn from this process to the umbilicus," but it is commonly spoken of as a little nearer to the iliac spine. There are eight Röntgen pictures in the book. Most of them show nothing useful, so far as we can see, but we are inclined to say the same of the great majority of the "skiagrams" with which medical publications have been adorned for some years past.

So much for the few points in the substance of the book that seem to us unsatisfactory; now for some of the verbal blemishes that we have noted. In common with almost all contemporary writers, Dr. Taylor says case when he means patient; he states that over half the "cases" of pronounced diabetes die of coma. Of course, this is simply carelessness, for he knows well enough that a case cannot die. He clings to the obsolescent word tinea, one that seems dear to the British heart; he says "Argvll-Robertson pupil," as if two men, one named Argyll and the other named Robertson had described it, in which case the use of the hyphen would be proper; and he employs the words morphia, atropia, and strychnia, which many years ago were dropped from the British Pharmacopæia, where they originated. On the other hand, we have to commend him for spelling lymphangeioma and leuchæmia correctly, although he does say "septicæmia.

The mechanical features of the book are most creditable to the publishers, and the index is excellent. The criticisms which we have made must not be interpreted as denoting that we have not a high opinion of the work; indeed, we regard it as of great value.

A Textbook of the Practice of Medicine. For Students and Practitioners. By James Magoffin French, A. M., M. D., formerly Lecturer on the Theory and Practice of Medicine, Medical College of Ohio. Third Revised Edition, Illustrated by One Hundred and Ten Engravings in the Text and Twenty-five Full Page Plates in Tints and Colors. New York: William Wood & Co., 1007. Pp. Nyil-1252. 1907. Pp. xxii-1253.

This edition has been so thoroughly revised that the book is practically a new one, and we therefore make no apology for devoting to it a considerable amount of space, especially as it is of such great excellence. Indeed, not since the late Dr. Austin Flint's treatise appeared have we met with a work on the practice of medicine, written by a single author, that has seemed to us so satisfactory as Dr. French's. We shall mention the features of particular merit that have attracted our notice, and certain others, of minor importance,

which we do not approve of.

In the first place the book is exceedingly comprehensive and the arrangement of subjects is a convenient one. The author is perfectly justified, we think, in advocating the open air treatment of pneumonia. He speaks well of placing the patient's bed in a tent, on a veranda, or on the roof, and says: "The relief experienced by the patient in a severe condition from removal to the open air is remarkable, and it undoubtedly makes recovery possible in many cases that are hopeless without it." He is justly conservative as to the use of tuberculin in the diagnosis and treatment of tuberculous disease. as we have before remarked (see the New York Medical Journal for July 11th, page 78). The refinements of its diagnostic use, such as by Calmette's ophthalmic application and by inunction, are not mentioned, but they have so recently been proposed that doubtless the sheets had gone through the press before sufficient observations had been reported to justify the author in treating of them. Dr. French's remarks on the climatic treatment of consumption are terse and in all respects judicious; in his brief mention of the compression treatment he speaks of the injection of sterilized air, oxygen, normal salt solution, and oil into the pleural cavity, but does not allude to that of nitrogen, which we think is worthy of some attention.

The article on exophthalmic goître is excellent, and it is illustrated with an unusually graphic picture (though roughly executed) of the facial expression met with in that disease. The author's description of "heart block" (page 617) is the best that we have seen. In our opinion, he correctly rates masturbation and sexual excesses as of little

importance in the ætiology of epilepsy

Most of the sections are introduced by admirably accurate and condensed paragraphs, each giving a definition and a brief synopsis of what is known concerning the history and geographical distribution of the particular disease treated of; and the final portion of the work, entitled Clinical Methods of Examination, is exceedingly instructive.

The book is disfigured by the "bobtailed" spelling, and we find some verbal errors that can hardly be accounted for by devotion to that fad—for example, "coagulæ" (page 90), "erysipelatus" as the genitive of erysipelas (page 218), and "scabei" as the genitive of scabies (page 503). These slips are offert by the correct use of perferating, instead of

"perforated" ulcer. We think that Dr. French greatly overestimates the danger of using humanized vaccine when he says that it "should never be employed except in case of emergency," and we believe that he misapprehends the reason for inserting vaccine at more than one point. It is strange to find it stated of bees, wasps, ants, and spiders that they "sometimes act as parasites." But the book so teems with meritorious features that the blemishes which we have pointed out may be lightly passed over. From the mechanical point of view, it is very creditable to the publishers.

Taschenbuch der Physiologie. Von Prof. Dr. med. H. BORUTTAU in Berlin. Helt 1 und Heft 2. Leipzig: Dr. Warner Klinkhardt, 1908. Pp. 243.

According to the publisher's announcement, this book constitutes the first of a series of students' note books designed to be used along with textbooks and lectures. The text is concise, and carries the student along merely the essentials of the various topics, the idea being for the student to fill in any additional data presented by the lecturer. For this purpose a very wide margin is provided, and also a number of blank pages. To graduates of the College of Physicians and Surgeons, the present book will appear strikingly like the bound volumes of one of the professor's lecture notes. The book is well illustrated with numerous drawings, most of which are original. The work should receive a warm welcome from the German student body.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Einführung in das Wesen der Magen-, Darm- und Stoff-wechsel-Krankheiten. Von Dr. Gaston Graul. Mit 2 Ab-bildungen im Text. Zweite, neu bearbeitete Auflage. bildungen im Text. Zweite, neu Würzburg: A. Stuber, 1908. Pp. 162.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commis-sioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending July 15, 1908:

ALTREE, G. H., Acting Assistant Surgeon. Excused from duty without pay for two months from June 4, 1908. ASHFORD, F. A., Assistant Surgeon. Directed to report to Passed Assistant Surgeon Foster, San Juan, Porto Rico, for examination for promotion to the grade of passed assistant surgeon.

passed assistant surgeon.

Catter, P. L., Acting Assistant Surgeon. Granted leave of absence for four days from July 6, 1908, under paragraph 210, Service Regulations.

ELDREDGE, N. B., Pharmacist. Granted leave of absence for six days from July 9, 1908, under paragraph 210, Service Psychology.

Service Regulations.

GLENNAN, A. H., Assistant Surgeon General. Granted leave of absence for twenty-eight days from July 22, 1908.

Manning, H. M., Assistant Surgeon. Directed to report to the director. Hygienic Laboratory, for temporary

Manning, H. M., Assistant Surgeon. Granted leave of absence for three days from July 12, 1908.

McKeon, F. H., Assistant Surgeon. Directed to report to

the chairman of the Board of Examiners, Manila, P. I. to determine his fitness for promotion to the grade of passed assistant surgeon.

NUTE, A. J., Acting Assistant Surgeon. Granted leave of absence for sixteen days from August 4, 1908.

PARKER, H. B., Passed Assistant Surgeon. Granted leave

of absence for one month from August 1, 1908.

Perryjohn, Jos., Assistant Surgeon. Directed to report to the chairman of the Board of Examiners, Manila, P. I., to determine his fitness for promotion to the

Rodan, J. C., Acting Assistant Surgeon. Granted leave of absence for seven days from July 14, 1908.

Salmon, T. W., Assistant Surgeon. Directed to report to the chairman of the Board of Examiners, Washington, D. C. Luke or 100 to determine his fitness for a recommendation. D. C., July 20, 1908, to determine his fitness for promotion to the grade of passed assistant surgeon.

L. T., Acting Assistant Surgeon. Granted leave SEAVEY,

of absence for twenty-one days from July 25, 1908.

SPRATT, R. D., Assistant Surgeon. Directed to report to the chairman of a Board of Examiners, Washington, D. C., July 20, 1908, to determine his fitness for promotion to the grade of passed assistant surgeon.

Sponn, A. E., Acting Assistant Surgeon. Granted leave of absence for thirty days from August 1, 1908, and excused without pay from August 31 to October 31, 1908

SWEET, E. A., Assistant Surgeon. Directed to report to the chairman of a Board of Examiners at San Francisco, Cal., July 20, 1908, to determine his fitness for

promotion to the grade of passed assistant surgeon. TAPPAN, J. W., Acting Assistant Surgeon. Granted leave

of absence for twenty days from July 8, 1908.

Trask, J. W., Passed Assistant Surgeon. Granted leave of absence for twenty-seven days from August 3, 1908. WALKER, T. D., Acting Assistant Surgeon. Granted leave

of absence for eight days from June 25, 1908.

RD, W. K., Passed Assistant Surgeon. Granted leave

WARD, W. K., Passed Assistant Surgeon. Granted leave of absence for seven days from July 14, 1908, under paragraph 191, Service Regulations.

WICKES, H. W., Passed Assistant Surgeon. Directed to proceed to Brunswick Quarantine Station, Georgia, for special temporary duty, upon completion of which to rejoin station.

Boards Convened.

A board of medical officers was convened to meet at Seattle, Wash., for the purpose of examining certain alien immigrants. Detail for the board: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W.

Chapin, recorder.

The board of medical officers convened to meet in San Francisco, Cal., on July 6, 1908, to examine assistant surgeons for promotion to the grade of passed assistant surgeon, was reconvened to meet on July 20, 1908. Detail for the board: Surgeon H. W. Austin, chairman; Passed Assistant Surgeon Rupert Blue; Passed Assistant Surgeon W. W. King, recorder.

A board of medical officers was convened to meet in A board of medical others was convened to meet in Manila, P. I., to examine assistant surgeons for promotion to the grade of passed assistant surgeon. Detail for the board: Passed Assistant Surgeon V. G. Heiser, chairman; Passed Assistant Surgeon T. B. McClintic; Passed Assistant Surgeon A. J. McLaughlin, recorder.

C., July 20, 1908, to examine assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for promotion to the grade of passed assistant surgeons for passed assistant surgeon.

geons for promotion to the grade of passed assistant surgeon. Detail for the board: Assistant Surgeon General geon. Detail for the board: Assistant Surgeon A. M. W. J. Pettus, chairman; Passed Assistant Surgeon A. M. Stimson; Passed Assistant Surgeon J. W. Trask, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending July 18, 1908:

BAILY, H. H., Captain. Ordered to Fort Wayne, Mich.,

for temporary duty, and return.

Bosley, J. R., Captain. Ordered to duty with First Infantry, en route to and at camp at American Lake. Wash. CARTER, E. C., Lieutenant. Relieved from duty at Fort Leavenworth, Kan., and ordered to duty at the expira-tion of his present leave of absence, at Fort Sheri-

dan, Ill. HARRIS, H. S. T., Major. Ordered to duty at the expiration of his present leave of absence at Fort Leaven-

worth, Kan

HUNTINGTON, P. W., Captain. Left Fort Rosecrans, Cal., on leave of absence for three months

on leave of absence for three months.

LAGADE, L. A., First Licutenant. Returned to Chief Surgeon's office, Denver. Col., from leave of absence.

MUNSON, E. L., Major. When relieved at Fort Sheridan, Ill., ordered to duty as instructor in the care of troops at the Army Staff College, Fort Leavenworth, Kan.

RAYMOND, T. U. Major. Left Fort Logan, Col., with Twenty-first Infantry for camp near Fort D. A. Russell Woo.

sell, Wyo. Woodbury, F. T., Captain. Arrived at San Francisco, Cal., from Philippine Service, and granted leave of absence for two months

The following officers of the medical corps have been

promoted to the rank of major, from April 23, 1908: Captains Henry Page, J. B. Clayton, I. A. Shimer, C. J. Manly, B. K. Ashford, W. P. Chamberlain, F. M. Hartsock, H. A. Webber, E. R. Schreiner, D. F. Duval, and David Baker.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending July 18, 1908:

ALEXANDER, C. E., Pharmacist. Appointed pharmacist from July 10, 1908; ordered to the Relief.
BIELLO, J. A., Assistant Surgeon. Detached from the Solace and ordered to the Pacific torpedo fleet. EYTINGE, E. O. J., Assistant Surgeon. Detached from the Concord and ordered to the Ranger.

HARMON, G. E. H., Medical Director. Detached from the Naval Academy and ordered to temporary duty in command of the Naval Medical School Hospital, Washington, D. C.

Washington, D. C.
KERR, W. M., Acting Assistant Surgeon. Detached from
the Naval Hospital, New York, N. Y., and ordered to
the Naval Hospital, Norfolk, Va.
LEE, A. E., Assistant Surgeon. Detached from the Naval
Hospital, Canacao, P. I., and ordered to the Concord.
McLarty, C., Pharmacist. Placed on the retired list from July 10, 1908, in accordance with section 1453, Revised

Assistant Surgeon. Detached from the RANDALL, R. C., second torpedo flotilla and ordered to the Solace SNYDER, J. J., Surgeon. Detached from the New Hamp-shire and ordered to the Franklin.

Births, Marriages, and Deaths.

Married.

TREATMENT OF LARYNGEAL STENOSIS, IN-CLUDING INTUBATION BY THE DORSAL METHOD*

> By Louis Fischer, M. D., New York,

Attending Physician to the Willard Parker and Riverside Hospitals.

It is unnecessary to burden you with statistics proving the virtues of antitoxine. Besides, all of you have no doubt, at some time in your practice, Because this pathogenic bacterium possesses marked virulence which may persist months after the disappearance of the disease in a given patient. Pathogenic bacteria may be harbored for a long time in the crypts and follicles of diseased tonsils, or they may be found in the throats of children with masses of fungoid granulations, such as adenoids.

Coughing, frequently sneezing will spread pathogenic bacteria, and if the Klebs-Loeffler bacillus has been dormant in the nose or throat it can be disseminated by the sneeze or by the cough.

In many children the Klebs-Loeffler bacillus is harmless. It is in the weak, in the subnormal, in

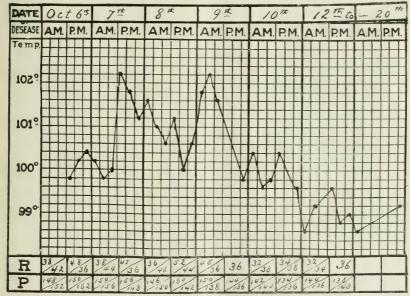

CHART 1.—F. W.; age seven months; ill two days. Received 0,000 units antitoxine on admission to Willard Parker Hospital. Was restless and croupy; showed slight retraction. No exudate in throat. No nasal discharge. Three cultures taken during first three days after admission were negative for Kichs-Loeffler bacilli. Patient improved until discharges. October 20th.

had occasion to verify the specific nature of antitoxine when used in sufficient quantity as a healing serum, or when injected to confer immunity as a prophylactic.

The Klebs-Loeffler bacillus is by no means extinct. This can be verified by walking through the wards of any hospital devoted to contagious diseases in this country or abroad. Why is this so?

*Read before the Harley, Wedical Society, January 8, 1008

the tuberculous, and in the strumous child that it will migrate from the surface into the body which does not contain sufficient antibodies to destroy the germ, and so the disease develops.

The presence of false membranes in the pharynx or tonsils does not necessarily mean an obstruction to respiration. If the larynx is not involved it is rare for the tonsils and pharynx to be so thickly covered with diphtheritic deposits as to mechan-

ically obstruct the entrance of air into the larynx. But, when in a narrow tube like the larynx there is an inflammatory thickening and infiltration, plus the deposit of psuedomembranes, then the narrow lumen is easily obstructed, preventing the entrance of oxygen and giving rise to that train of symptoms which is termed laryngeal stenosis.

Some children are more prone and more susceptible to laryngeal stenosis, first, by reason of their anatomical weakness, that is, structural weakness

vital organs, so also it is possible for a streptococcus or a Klebs-Loeffler bacillus, or an influenza bacillus to give rise to an infection in which the clinical manifestations are alike, giving rise to a laryngeal stenosis. Laryngeal stenosis is a condition not to be trifled with. The delay of several hours, until a culture shows that we are dealing with a dipheritic stenosis or a streptococcus stenosis or an influenza stenosis, may prove fatal for the patient.

Acute laryngeal stenosis is never found in syphilis.

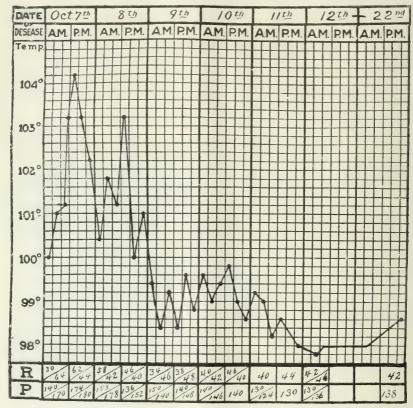

CHART 2 B. H.; twenty-two months old; ill two days; admitted to Willard Parker Hospital, October 7th. On admission had croup retraction. Throat congested. Slight exhibite the on left tonsil. Nasal discharge. Primary culture showed presence of Klebs Loeffler bacili. Received 10,000 units antitoxine and Dover's powder, gr. 2. October 5th. Compt. Condition poor. Received 10,000 units antitoxine. Strychnine gr. 1/120, caffeine gr. 2, q. 3 h. Deser's powder gr. 2. October 1th Condition unproved, less croup. Condition slowly improved under stimulation.

found usually in rachitic, syphilitic, and those children of the strumous, scrofulous, or tuberculous type, or those having the so called "status lymphaticus."

The bacteriological diagnosis of laryngeal stenosis is not always easy to determine, first, because the location of the larynx prohibits in a measure the proper taking of a culture, therefore the diagnosis must be made by the clinical symptoms. We also know that just as several varieties of pathogenic bacteria may cause inflammatory symptoms in other

When this condition is met with, the history and the congenital manifestations are so different that one cannot be misled into the belief that he is dealing with an acute process.

At all events, disregarding the bacteriological data the treatment is identical. With a fractured bone, no matter what caused the fracture, the treatment is always the same. So also must the treatment of a laryngeal stenosis be the treatment of the effect rather than the cause of the disease.

A Diagnostic Point. If a child appears in good

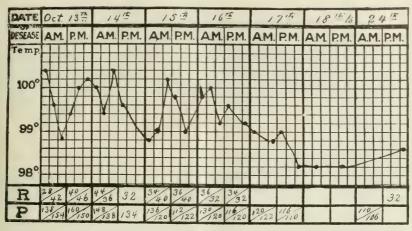

CHART 3.—R. F.; two and a half years old; ill two days; admitted to Willard Parker Hospital, October 13th. On damission was croupy, with moderate retraction. Pulse of good force. No cyanosis. Received 10,000 units antitoxine and Dover's powder, 2 gr.. Croup lasted three days. Primary culture negative for Klebs-Loeffer bacilli. Secondary cultures showed one positive for Klebs-Loeffer bacilli on October 20th. No exudate in throat or nose. Fauces congested. Discharged cured on October 24th.

health and awakens suddenly at night without having given evidence of disease the day before, such croup is *usually* of the catarrhal type and is not to be classed with that serious form of laryngeal

stenosis due to diphtheritic pseudomembranes. Diphtheritic laryngeal stenosis usually appears slowly. It comes on gradually. A child with diphtheria usually shows malaise during the period of

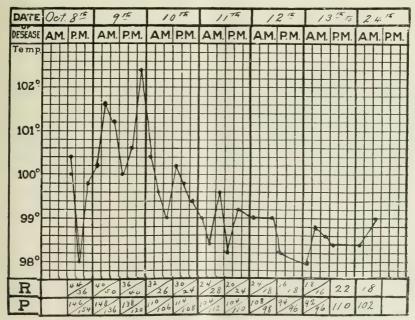

CHART 4.—L. G.; four years old; admitted to Willard Parker Hospital, October 8th, Had croup and retraction on admission. Throat congested, tousils enlarged, no exudate, slight nasal discharge. Examination of heart negative. Examination of lungs showed sufficient air posteriorly. Primary culture showed presence of Klebs-Loeffller bacilli. Initial dose of 10,000 units antitoxine was repeated with 5,000 units on the following day. Croup cleared rapidly after second injection. Small trachesi cast coughed up a few hours after admission. Patient discharged October 24th.

incubation for a few days, and anorexia. The glands of the neck (cervical glands) are swollen, the temperature is rarely high, the pulse is rapid. A laryngeal cough of a hoarse or barking character appears, and the croupous character is more and more intensified, until we notice labored breathing, then we note the accessory muscles of respiration coming into play, and the thorax shows the great struggle that is necessary to properly oxygenate the lungs. Cyanosis may also appear. The child in its struggle for oxygen cannot lie on its back, but must sit up. Each effort at inspiration is a struggle.

The worst symptom encountered next to the

immediate intubation. (See cases from hospital.)

It a child lives at a considerable distance from the physician, and suffers with laryngeal stenosis, it is far better to introduce a tube and relieve such stenosis, rather than to run the risk of suffocation.

When such conditions are noted, the pulse should be our guide as to the urgency of intubation. A very rapid pulse, or one becoming thready, or an intermittent pulse are danger symptoms which demand relief. Procrastination means death, hence it is wise not to resort to emetics and thus delay the chances of recovery.

In the treatment of larvngeal stenosis three im-

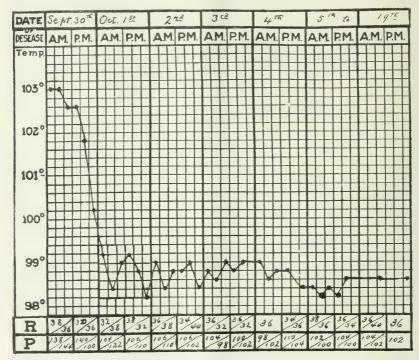

CHART 5.—M. S.; fourteen years old; ill seven days; admitted to Willard Parker Hospital, September 30th. Had croup and retraction on admission. Received 10,000 units of antitoxine and 2 drachms of whiskey; 10,000 units antitoxine repeated the following day. Croup lasted about three and one half days, with gradual improvement. No exudate in throat, but nasal discharge present. Culture of nose and throat showed the presence of Klebs Loeffler bacilli. Examination of heart and lungs negative, save for a few mucous rales at bases posteriorly. Discharged October 19th.

respiratory difficulty is the effect on the heart. The pulse is usually very feeble and markedly accelerated. Death may occur if relief is not given promptly. Therefore the pulse should be carefully studied in determining the urgency of the intubation.

Intubation. There is a vast difference between intubation in private practice and as practised in the hospital wherein experts at intubation are continuously on duty. Laryngeal stenosis with constant supervision in a hospital will frequently be treated by giving large doses of antitoxine sufficient to overcome to a majority and sufficient to stimulate glandular activity in the body, and without reserting to

portant points should be remembered: They are, first, to relieve the stenosis by intubation and thereby prevent asphyxia; second, to inject sufficient antitoxine to neutralize the toxemia present; and third, to restore inactive functions by nutrition and by hygienic means, also giving the required amount of stimulation to strengthen the heart and stimulate all the emunctories to activity.

It is well to be reminded that we must not pin our faith to the absolute curing of each and every case of laryngeal stenosis after a large dose of antitoxine has been injected, and perhaps intubation performed for the relief of the stenosis. Unless sufficient at-

1.-The mummy bandage showing child in proper position to the dorsal method

tention is given to restore the body to its previous good health we must not be surprised to find that the stenosis will recur and require the continual use of an intubation tube.

Dorsal Method. The upright method, which is the older method and the one advocated by O'Dwyer, is still in use by the older intubators. The modern method, and the one in use at the Willard Parker Hospital and also at the Riverside Hospital is the dorsal method. The dorsal method is easier because in an emergency the physician can intubate without many assistants.

To intubate properly, one must be prepared. No details should be neglected. Obturator, introducer, and tube should be inspected so that no time is lost when once the introduction of the tube is attempted. The great exhaustion of the strength of the patient, due to deficiency of oxygen, and from the forcible attempts at respiration are very perceptible. There is usually cyanosis present.

Force should never be used during intubation, excepting when we deal with that very rare condition known as subglottic œdema. The introducer should always be held lightly between the thumb and forefinger. Force is entirely unnecessary. The

finger should be kept in contact with the distal extremity of the tube directing it a little obliquely towards the right side of the larvnx. It is necessary to get inside the left aryepiglottic fold, especially in very young children.
False Passage. Repeated

forcible attempts at intubation will lacerate the tissues. It is not infrequent to enter the ventricles of the larynx producing a false passage by such forcible attempts at in-

tubation.

If a false passage has been produced and we are unsuccessful in our attempts at intubation then it is much wiser to resort to tracheotomy, rather than risk the danger incident to exhaustion from both the deficient oxygenation and the heart strain in the struggling child. This advice is in line with the teachings of O'Dwyer.

Many cases of larvngeal

stenosis recover without resorting to intubation. It is necessary to begin with very active treatment. First and foremost, sufficient antitoxine must be injected to overpower the toxemia which may result fatally. We must not expect to find a specific effect too soon. Nature's effort to restore normal conditions is evidenced by the exfoliation or the shedding of the pseudomembranes. While this loosening of the

false membranes may occur within twenty-four to forty-eight hours, some cases may show retarded exfoliation owing to a lowered vitality from this infection, and herein lies the great danger. This danger consists in blocking of the narrow laryngeal tube, thus causing an impediment to proper respiration. Great good can be accomplished by introducing a proper sized tube. Harm can be done by introducing a tube that does not fit, and it is chiefly to improper fitting tubes, and also to unskilled manipulation of good and proper fitting tubes, that most cases of retained tube are due.

Some children with slight croup may improve after several days and not require intubation. On the other hand, croup may be suddenly increased and demand immediate intubation to prevent fatal

asphyxia.

The weakness of the system during an attack of diphtheria can best be appreciated by studying the relative proportion of the red and white blood cells. It has been found that the toxine of diphtheria not only destroys the red blood cells and gives rise to a marked leucocytosis, but it also produces a decided atony of the muscular structures of the body. To restore normal conditions no drug equals strvch-

nine. This should be very liberally prescribed from the beginning of the illness. It is especially indicated during convalescence. The system will tolerate far greater doses after passing through an acute infection, and I frequently find that a child several years old can take 1/50 grain three times a day and oftener to advantage. I believe that the toxæmia of a diphtheritic infection creates a tolerance of large doses of strychnine without harm and with apparent benefit.

Recurring Laryngeal Stenosis after Intubation. This is usually caused by forcibly pushing the tube into an edematous or infiltrated mucous membrane. O'Dwyer says that it is caused by using a tube that is too large for the lumen of the larynx, usually in the hands of inexperienced operators. Metallic

tubes that have been worn for a long time contain large calcareous deposits; the latter are a deposit of lime salts, contained in the diphtheritic membrane. When removing such a tube during extubation the mucous membrane is easily lacerated, and thus ulceration is caused thereby.

"The cause of persistent stenosis following intubation in laryngeal diphtheria, can be summed up in the single word 'traumatism.' Paralysis of the vocal cords may possibly furnish an occasional exception to this rule."

Thus an injury to the larynx can be done by a

Fig. 3.—Intubation. Second step in the operation. Handle of the introducer elevated; the tube sinking into the larynx as the handle of the introducer is elevated.

tube that does not fit; it may result from an imperfectly constructed tube, or from a perfect tube that is too large for the lumen of the larynx, although proper for the age, or from a tube that is perfect in fit and make, if not cleaned at proper intervals. O'Dwyer states that the seat of the lesion that keeps up the stenosis is just below the vocal cords in the subglottic division of the larynx, or that portion of the organ bounded by the cricoid cartilage. Exceptions to this rule result from injury produced by the head of the tube on either side of the base of the epiglottis, just above the

ventricular bands. The reasons given by O'Dwyer for the existence of the stenosis at this particular portion can best be explained by the following:

Anatomically normally there exists a constriction in the cricoid region, when the mucous membrane infiltrates or gets ædematous, it swells to such an extent and only towards the centre, as the outside is surrounded by cricoid cartilage, and while swelling towards the centre, mechanically impedes respiration and thus calls for mechanical relief, i. e., intubation. O'Dwyer states that if a tube is forced in a larvnx in a case of this kind, ulceration and sloughing of the tissues is inevitable, and in some instances necrosis of the cricoid cartilage can result from interference with the circulation. Our only

1. 3 Let let e. Let be on the operation. The estractor is guided along the left index every note the beak enters the lunes of the tube.

safeguard in preventing too much mechanical injury, as in the condition above cited, is to introduce 'a tube of small calibre." In the early stage of this class of cases the dyspnœa returns slowly; sometimes several days or in some instances only a few hours may pass before the former condition of laryngeal stenosis is recognized, and the necessity for the introduction of a proper tube is demanded. When the dyspnœa returns slowly it means that the lining membrane of the larynx cannot swell while the tube is in position, because it is compressed between the tube and the cartilage; it requires some time for the reappearance of the cedematous tissue, which drops into the chink of the glottis, and obstructs the respiration, the latter condition being mechanically prevented as long as the tube is

in situ. Exceptional cases have been reported where granulation tissue springs up from the anterolateral aspects of the larynx just above the ventricular bands. O'Dwver states that the origin of this growth is a slight ulceration or erosion of the mucous membrane at the points corresponding to the greatest transverse diameter of the shoulder of the tube from the pressure exerted during the act of swallowing.

Paralysis of the vocal cords, although known to exist, is very hard to diagnosticate without a proper laryngoscopic examination. Like other forms of paralysis, it comes very late in the course of the disease, and if, after wearing an intubation tube a short time, laryngeal stenosis recurs, it is safe to assume that paralysis of the vocal cords is not the cause of the immediate recurring stenosis

How can we prevent recurring laryngeal stenosis in ordinary membranous diphtheria? Every tube must be introduced in the gentlest manner possible. The slightest force exerted will lacerate the tissues. It is a wise rule to remove the tube every five days. If a tube must be introduced more than twice, the writer has adopted the plan mentioned by O'Dwyer, and which is not mentioned even in recent textbooks. It consists in taking a rubber tube, immersing it in a solution of hot gelatin containing twenty-five per cent. of powdered alum, and thus introducing the tube with this covering of alum gelatin. The writer has also had quite some experience with the beneficial results of a twenty per cent. solution of ichthyol gelatin, as a covering for the rubber tube. In the same manner a film consisting of hot paraffin and iodoform or europhen (diisobutylcresol iodide), 3 per cent., was applied in another case with very good results. This intralaryngeal medication, by applying the drug to the affected ulcer on the inside of the larynx by means of the intubation tube, has proved of some value in a few cases seen by the writer.

Let me sound a note of warning against haphazard intubation. The operation in itself requires some little skill, but chiefly a thorough knowledge of the details of the special anatomy of this region.

If an unskilled operator must intubate, then a hypodermatic injection of 1/100 grain strychnine or 1/2 grain tablet caffeine sodium benzoate may be given prior to the operation. It is also wise to have a mustard foot bath ready to stimulate the circulation in case of collapse. If the circulation does not improve after the mustard foot bath given at a tem-

Fig. 5.—Extubation. Second step in the operation. The beak of the extractor holding the tube firmly. The operator withdraws the tube.

perature of 100° F., then a hot saline colon flushing at a temperature of 115° to 120° F. may be given.

It is self understood that such remedies are to be used as emergency in case of collapse and not otherwise. Fresh air must not be forgotten, hence the windows should be open top and bottom. This will give all oxygen necessary.

In the treatment of extubation with recurring laryngeal stenosis, especially in a very nervous and fretful child, I order some antispasmodic treatment twenty-four hours before extubation. From five to ten grains sodium bromide, depending on the age, may be given in water or in milk, every three hours. Codeine, one tenth to one fourth grain, depending on the age, may be given during the evening before extubation, to insure rest and quiet to the nervous system.

A METHOD FOR PREVENTING INFECTION FROM THE SKIN DURING SURGICAL OPERATIONS.

By J. Shelton Horsley, M. D., Richmond, Va.,

Professor of the Principles of Surgery and Chineal Surgery in the Medical College of Virginia; Surgeon to Memorial Hospital.

The great danger of infecting a wound from the skin has been recognized since the beginning of aseptic surgery, but the significance of such an infection from the deep layers of the incised skin has

Fig. 7. TI - mersion in the cardboard which represents the skirl A towel has been tricked over the edge of our half of the incision and fastened in position.

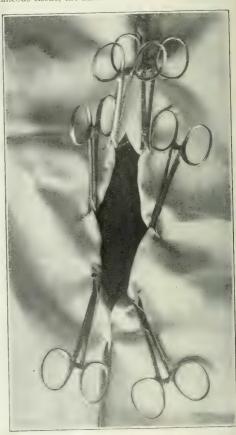

been emphasized chiefly within the past few years. Some German bacteriologists assert that a large portion of infected wounds in previously clean cases are due to this source. The surface layers of the epithelium are generally rendered sterile by the usual methods. The desirability of not causing injury to the skin by stiff brushes, by prolonged soaking with wet dressings, or by the use of too strong chemical solutions, is generally recognized at present. Such measures tend to weaken the resistance of the skin, and, at the same time, cannot reach the germs in the sweat glands, in the sebaceous glands, or in the hair follicles. If the skin is not injured, or is not to be incised, the germs in these deep structures will rarely reach the surface within the their period of time required in an ordinary opera-

tion. But when the skin is incised, the sweat glands, sebaceous glands, and the hair follicles are necessarily laid open, and bacteria, being no longer restricted by the ducts of these glands, have free access to the wound. It is the practice of many surgeons to use one knife for incising the skin, and then lay this knife aside and complete the operation with other instruments. It must be recognized, however, that if the knife is infected the edges of the incised skin are also infected, and the further manipulations necessary to the performance of the operation will tend to carry bacteria from the incised skin deep into the wound.

In order to obviate this defect in technique, I

have adopted the following procedure:

After making the incision in the skin and subcutaneous tissue, the knife that has been used for this

1) - Bath, ode of the incroon are here shown protected by towels. At each end of the incroon the towels are held together is that the towels.

purpose is laid aside and not used further. Then a towel, folded in the middle so as to give a double thickness, is tucked around the edge of the skin and fastened in this position by small tenacula, usually three tenacula on each side are sufficient. It is

important to fold the towel well over the edge of the skin. Small safety pins may be used instead of the tenacula. A short distance from the angle of each wound the two towels are clamped together with a hæmostatic forceps, as shown in the second photograph. By this method not only is all of the skin surface covered, as in cases where adhesive rubber dam is used, but the cut edges of the skin, where the glands and hair follicles have been exposed, are fully covered by the towels—a feature that is not accomplished by any other method with which I am acquainted.

Fig. I shows an incision in cardboard, which represents the skin. The towel is being folded over the cut edges with two of the tenacula in place. In Fig. 2 the towels have been fixed in place on both sides of the incision, and the hæmostatic clamps have

heen applied.

This method of protection from skin infection may be used in operations in any part of the body, but it is particularly suitable for abdominal operations.

SARCOMA OF THE TONSIL.*

Report of a Case, Operation, Pathological Findings.

By John Edwin Rhodes, M. D.,

Chicago.

S. W. F., a traveling salesman, was referred to me December 6, 1907, for operation upon a tumor of the left tonsil. He was a man thirty-five years of age, married, the father of a healthy child, and apparently a man of robust health except for the condition of the throat. He gave me

the following history:

In July he was first conscious of any trouble in the throat. He noticed at that time some fulness and at first a considerable amount of pain, which persisted for a short time only. There was occasional pain now, but not of a severe character. There was none from external pressure at the angle of the jaw. The pain was of a dull, aching character and not constant. He had been losing in weight for some time and was about fifteen pounds below his normal weight of one hundred and eighty-eight pounds. His appetite was good and his digestion normal, but the present size of the growth somewhat interfered with deglutition. His strength was as good as usual, and he had followed his avocation up to that time. He had had local treatment by his physician since August, but the growth had continued to increase slowly in size, although the discomfort had been somewhat ameliorated by the applications. Recently, however, he had complained of an increasing difficulty in breathing, interfering with his rest-at night, which was broken by many choking sensations, and he had been obliged very recently to sleep in a half reclining position to get any rest at all. His greatest fear was that he would choke to death in one of the spasms of dyspinca. He had been a little hoarse at times, but the functions of the larynx seemed not to be affected. There had never been any external swelling. He had never had any severe illness, and there was no history of lues. He had had an occasional sore throat.

He recalled a local application made to his tonsil six years ago by a physician, who used a piece of wire and injured the tonsil in swabbing it, and it did not heal for some time afterwards. He never used alcoholics to excess, but had been a confirmed tobacco user. He had a small mass of fine cut tobacco in his left cheek almost continuously from the time he arose in the morning until he retired at night, often swallowing the saliva. He chewed five cents worth of fine cut tobacco every two days, and smoked a pipe or a half a dozen cigars daily in addition. This had been his habit for many years. His

father died at sixty-two, of diabetes; his mother was living, sixty-two years of age, and well. He had four brothers living, aged, respectively, thirty-three, thirty-one, twenty-seven, and sixteen. Two sisters were living, aged twenty-three and twenty-one. Two sisters died, one in infancy and the other aged thirty-three, of typhopneumonia and spinal meningitis. One of his sisters was treated for goirre

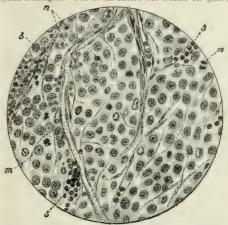

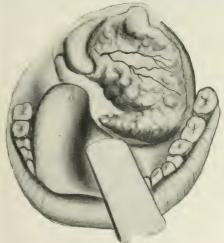

Fig. 1.—Alveolar sarcoma of the tonsil. The drawing shows a typical field, illustrating the alveolar structure, with strands of stroma running between the individual cells. a year ago, and cured, and one brother was being treated for the same affection. The patient was of a very nervous temperament. He had had some bleeding from the throat every morning but of small amount. His temperature was 99° F., and his pulse 96, and regular. The tongue was clean and its motility normal. There was no headache or dizziness.

On examination I found no enlargement of the glands externally about the angle of the jaw or neck. The nasal cavities were free. On depressing the tongue a tumor of the left tonsil was shown, situated within and extending

F16. 2.-Showing sarcoma of the tonsil

^{*}Read at the thirtieth annual congress of the American Laryngoogical Association at Montreal, Canada, May 11, 1908

from the tonsillar space outwards two thirds across the fauces, attached only within the tonsillar triangle. The lower part of the growth hung over the base of the tongue as far as and impinging slightly on the epiglottis. This tumor was irregular in outline, smooth on its surface, but somewhat lobulated, pinkish in color, rather easily penetrated by a smooth, flat, blunt probe, and bleeding quite easily. Bloodvessels indistinctly showed over the surface of the tumor. The patient gave a history of an obstinate hamorrhage in childhood from a wound in the foot, several days after the injury, but there was no reason to think he had a hæmorrhagic diathesis. I decided it would be much safer to provide a bloodless field for operation, tipossible, having in mind the tendency of similar growths in the throat to bleed, sometimes alarmingly, at the time of operation, and recalling the statement of Chevaliet Jackson last year that external carotid ligation may be of use not only to forestall hæmorrhage, but to inhibit growth I determined upon the preliminary ligation. Inasmuch however, as collateral circulation is quickly established, I cannot see that there is much to be hoped for in the inhibition of growth in these tumors, although from the fact he emphasized that sarcoma spreads by the vessels such. An operation was desired by the patient at once to religent the contraction because the contraction of the patient at once to religent the difficulties of the children the

An operation was desired by the patient at once to relieve the difficulty of breathing. On the eighth of December I sent him to the hospital for operation. Because of the great difficulty in breathing I decided to operate entirely under local anæsthesia. The patient was tractable and brave. The first step in the operation was to ligate the external carotid, which was done by Dr. Freer.

My friend Dr. J. Gordon Wilson, at the University of Chicago, has made some painstaking investigations regarding the blood supply of the tonsil, and he tells me that the blood supply in every case he has ever examined, has been so definite that there can be no doubt, in his opinion, as to what it normally is. The main blood vessels, the tonsillar, come from the facial, either directly, or from the ascending pharyngeal ramus. This artery, or the tonsillar, arises from the facial soon after its origin from the external carotid. The tonsillar artery passes through the pterygopharyngeal space towards the deep surface of the tonsil. In the fibrous tissue which surrounds the gland, it divides into two parts, one branch ascending to its upper pole, the As these arother downwards to the lower one. teries pass outwards from the middle point of the tonsil, that is into the tonsillar tissue, they divide into a great number of small branches, each lying in a considerable amount of fibrous tissue, derived from the fibrous investment of the tonsil. A number of English and American textbooks state that the blood supply also comes from the lingual and This is the case in some of the lower the palatine. animals, but it is not so in man. The lingual sends a branch to the anterior pillar, the ascending palatine to the posterior pillar, the descending palatine branches go to both. Obviously, therefore, the ligation of the external carotid should afford a practically bloodless field for operation, unless there should be an anomalous distribution of the blood vessels. After the ligation of the external carotid artery, bearing in mind that the ligature must be nearer the trunk of the common carotid than two centimetres, to include the facial, which sometimes arises by a common trunk with the lingual, there are two possibilities of hæmorrhage, notwithstanding the ligation, first from one of the arteries in the pillars and second, an abnormal tonsillar branch. as cases have been recorded of the origin of the tonsillar artery from the external carotid directly. A hæmorrhage might take place from the latter if

the external carotid were ligated above the origin of the tonsillar. Care should be taken to ligate close to the origin of the vessel, therefore. In order to facilitate this procedure it is customary to have the patient's head strongly thrown backward while he occupies a position on his back with his face turned slightly away from the operator. This lifts the artery towards the surface, and raises the jaw and submaxillary glands up out of the way, thus giving a wide operative field.

In this patient the ligature of the artery was made extremely difficult because he had to keep his head flexed and chin lowered, in order to breathe. This brought down the submaxillary gland in front of the trunk of the external carotid artery and made it necessary to hunt for the vessel in the lowest part of a deep pocket created by the larynx, sternomastoid muscle, and the lower jaw.

The incision was made along the anterior border of the sternomastoid muscle, beginning above the angle of the jaw and extending to the cricoid ring, after injecting freely of a two per cent. cocain solution. After division of the platysma fibres the first object seen was the submaxillary gland, which covered the arterial trunk and had to be dissected out of its bed and retracted upward in order to render the vessel accessible. The next important structure to appear was the facial vein, which was liberated and pulled downward out of the way.

Some small glands were then dissected out and by working upward the digastric tendon was at last brought to view with the hypoglossal nerve following its lower border. Even then the artery was not visible and its pulsation had to be felt for in order to expose it.

In ligating the external carotid artery it is important to avoid including the ramus descendens of the hypoglossus nerve in the knot and to tie the arterial trunk below the origin of its second branch, the ascending pharyngeal. The ligature may be between the stems of the superior thyreoid and ascending pharyngeal arteries. The retractors used in holding open the wound should draw the facial and superior thyreoid veins downward, and the internal carotid muscle, hypoglossal nerve, and submaxillary gland are pulled upward, out of the

A common impression prevails that ligature of the external carotid artery is an easy matter. This is not always the case although the operation is sufficiently easy so that any laryngologist can acquire the technique by a number of operations on the cadaver. The operative field is circumscribed by the submaxillary gland, facial vein, digastric muscle, hypoglossal nerve and larynx, so that there is little room, and no matter how long the skin incision be made the work must still be done in the deep, small area confined by the structures mentioned and filled with important nerves and yessels.

Palpation is a great aid in finding the vessel, if the pulse is strong enough to make its pulsations evident. The operation, except in children, may always be done under cocaine anæsthesia.

The technique proposed by Dr. Jackson is to expose the common carotid first, then follow up to the bifurcation, and ligate between the superior thyreoid and the lingual, bearing in mind the anomalous distribution that sometimes obtains, the giving off of these arteries from the common carotid, and the danger of ligating the common carotid. In this case the difficulty of breathing from the presence of the large tumor made it necessary to follow the plan I have indicated in my report.

I am of Dr. Jackson's opinion that external caro-

tid ligation is something to which laryngologists should resort more frequently in the removal of growths such as this, and hereafter I shall not feel quite safe in doing these operations without it.

After the ligation had been completed, injections of adrenalin (1 to 1000) and a two per cent. solution of cocaine, equal parts, were freely made into the base of the tumor through the outward part of the anterior pillar. I first freed the growth as thoroughly as possible from the anterior pillar, with a right angle knife, bent on the flat, with sharp cutting edges and point. As there was no bleeding, I did this boldly, both anteriorly and posteriorly, and then loosened it above as thoroughly as possible, so that I had the growth very well enucleated above before beginnad the growth very well enucleated above before beginning to excise the tumor. As the growth interfered a good deal with the patient's breathing, and he retched so constantly, it was not possible to remove it in one piece, so I dissected it out in fragments. In the upper zone there was no hæmorrhage, and I succeeded in almost completely removing the growth from the lower without much bleeding In clearing up this, however, I was anxious to remove every suspicious looking mass, and this was done by seizing it with notched forceps, drawing it outward, and excising only the part thus seized. A small fragment was thus removed at the central and posterior part of the lower zone of the space and a very severe hæmorrhage took place immediately. Compression was resorted to at once, and I saturated a piece of gauze with the adrenalin and this was held firmly into the bleeding point. The patient fainted very speedily, becoming very pale, and almost pulseless, when, to our relief, the bleeding ceased. He was immediately put to bed in a sitting posture and strict quiet enjoined. In about two hours he wanted to lie down, and in so doing another hæmornhage took place, but it did not recur afterward. He rallied well, and was soon able to sit up. A ligature abscess was the only complication of the external wound, and the site of the tumor soon cicatrized over nicely. I found, however, that the interrupted operation had left a mass of the growth in the upper angle. removed this at the office on December 26th, cutting deep down to muscular tissue and leaving no suspicious looking

I then felt that the operation was satisfactorily radical. It created very little pain, except once, when I found it necessary to cut through and remove part of the posterior pillar, and then the pain was very severe, but only as the excision was being made. He left the hospital on December 29th for his home in excellent condition, with the wound well and firmly cicatrized, and pulse and temperature normal. I placed the excised tissue in the hands of Pro-fessor H. Gideon Wells, of the University of Chicago laboratories, and he furnished me an excellent microscopi-cal study. He reports:

No traces of normal tonsillar tissue can be detected in any of the sections cut from various parts of the growth, which is of uniform structure in all parts examined. It consists essentially of a solid mass of cells, which are everywhere much alike, forming a solid cellular growth in which there is a slight but very imperfect tendency to alveolar arrangement. The stroma is not abundant, con-sisting of narrow bands of mature fibrous tissue about the larger vessels, from which slender anastomosing processes pass out at irregular intervals, tending to subdivide the tumor into imperfect alveoli. By special connective tissue stains (Mallory's aniline blue and Van Giesen's stain) fine fibrils may be seen occasionally within these atypical alve-oli, among the tumor cells, but they do not form a distinct oil, among the tumor ceils, but they do not form a distinct reticular structure as in a typical lymphosarcoma. In the larger connective tissue bands are numerous small, deeply staining nuclei, "lymphoid cells"; also, very rarely, an occasional eosinophile cell. The bloodvessels are not conspicuously abundant, but all the connective tissue bands with a characteristic structure of cerell worsels which exist as the supportive structure of small vessels, which always have a distinct endothelial lining and a connective tissue adventitia; no vessels can be found within the alve-oli, and there is no free blood and no blood pigment. The larger vessels have a distinct media. It is apparent that this vascular arrangement is adequate for the nourishment of the tumor, since nowhere can there be found the slightest evidence of necrosis, or even of less severe retrogressive changes. There is also a total lack of evidence of include, thate, either old or recent, and there is no inflammatory There is also a total lack of evidence of hæmorreaction whatever, no leucocytes at all being found, either free or in clumps

The free surface of the tumor is in part covered by the stratified epithelium with occasional short processes running down into the deeper tissues, characteristic of the surface of the normal tonsil. This epithelial layer rests upon a layer of loose connective tissue in which occasional isolated tumor cells are seen, but they do not penetrate the epithelium, except in a few places where an island of tumor cells occurs free in the epithelial coat. Much of the free surface is, however, devoid of epithelium, which seems to have been destroyed by a gradual pressure atrophy rather than by necrosis and ulceration, which is shown by the gradual thinning of the epithelial cells and the absence of inflammatory reaction. The denuded surface of the tumor is remarkable in the absence of evidences of infection and inflammation; it is covered by a very thin layer of hyalin fibrin mingled with a small amount of necrotic cells and stroma, and enclosing a small number of leucocytes; the total thickness of this surface layer of degeneration is, however, not much greater than that of the normal epithelial covering. Just beneath the surface of the tumor tissue shows a relatively large proportion of stroma, and some of the small vessels are thrombosed.

The cells of which the tumor growth itself is composed are of very uniform nature throughout the tumor. They are cells of very uniform nature throughout the tumor. They are cells of medium size, having a nucleus about twice the diameter of the small lymphoid nucleus, and a considerable amount of cytoplasm, which in this poorly hardened tissue is quite granular. The shape of the cells is entirely dependent upon the pressure of the surrounding cells, therefore they are polyhedral. The nuclei are of circular outline when not modified by pressure, and of a rather vesicular type in the mature cells, having a distinct nuclear wall, one to three deeply staining spherules, and a very small amount of chromatin as granules or threads. Vounger cells are of chromatin as granules or threads. Younger cells are more rich in chromatin. Rarely a cell is found with two nuclei, but there is no formation of multinuclear giant cells, or of cells with a single giant nucleus. Karyokinetic figures are very abundant, frequently half a dozen being seen in a single field (1/12th immersion lens); most of the figures are regular, but occasionally heterotype mitoses (characteristic of malignant tumors) may be seen. There are a very few cells showing disintegrated and fragmented nuclei, often associated with a hyaline transformation of the cytoplasm. Eosiniphile and plasma cells are not present among the tumor cells, although they are very occasionally found in the stroma.

The diagnosis is round cell sarcoma, of alveolar type The vesicular nuclei, the considerable cytoplasm, and the alveolar arrangement, suggest carcinoma; however, against this diagnosis are: (I) the intimate relation of the cells to the stroma, which almost forms a reticular network within the imperfect alveoli; (2) the homogeneity of the structure; (3) the small proportion of mature stroma; (4) the absence of any attempt at formation of tubules or ducts; (5) the total absence of necrosis and inflammatory reaction, which indicates a close relation between the tumor cells and the blood vessels. On account of the abundance of mitotic figures it is evident that this tumor is exceptionally

After I had received this report of the pathologist, on January 29th, thirty-four days after the last operation, the patient presented himself again for examination, and I found a confirmation of the exceptionally malignant character of the growth, clinically, in a tumor in a new site upon the left lateral wall of the pharynx, behind the posterior pillar, about five centimetres in length, two and one half centimetres in width, and a centimetre in thickness, extending upward behind the soft palate and downward to the vestibule of the larynx. As there were no symptoms of the vestibule of the larynx. As there were no symptoms of obstruction to breathing at this time, or to be apprehended in the immediate future, I refused to operate, promising the patient to do so if there should be danger of his choking to death hereafter. I then advised him to return home to his city and submit himself to treatment by the x ray, and, if possible, to take the Coley toxines. I have not seen the patient since that time, but his physician informs me that he has been having the x ray treatments, with apparent benefit, and is in good health at the present time. In view of the laboratory findings and the clinical history of the case, however, I am not optimistic as to the eventual cure of the disease.

SYPHILIS COMMUNICATED IN ASSAULT AND BATTERY.

By Harry G. Watson, M. A., M. D., New York.

There is no doubt that the occurrence of syphilis in the innocent added to the confusion as to its ori-

gin for several hundred years.

The history of syphilis antedates the discovery of America, but, by many, the beginning of it is associated with this great event. It is probable that the nature of the disease was not recognized until this time, as most authors give the year 1494 as the correct date of its discovery. There is sufficient interest in studying its history to trace the etymology of the word syphilis, and learn that this direful discase was embodied in a myth by a Veronese physician of the fifteenth century.

He relates in a poem that a herdsman, Syphilus by name, was afflicted with this malady by Apollo in punishment for paying divine homage to the king. How different it is in the twentieth century! It is a prosaic fact that most cases of syphilis to-day are imposed upon man by Venus for worshipping at

the shrine of a "queen."

During the sixteenth century a sudden prevalence of this infectious disease could not be accounted for by the populace nor explained by the physicians. Many believed its origin to be venereal, but this source alone seemed insufficient to account for the rapid spread of this affliction. The stars of the firmament were blamed by some of the people, and by others, since nuns and monks as well as those high in the Church were affected, the air was considered the medium of contagion; while others

thought it to be an offspring of leprosy. The infectious nature of the disease soon attracted attention to the different avenues of contagion, and it was ascertained that a sore or ulcer on the penis was concomitant with the disease, and a forerunner of many varied outbreakings on the skin. The sore was usually venereal; but experiments by inoculation showed a more important fact, and that was that it made little difference upon what part of the integument this sore occurred, whether on the head of the penis or the head of the person, the results from the infection were practically the same. This was the step that cleared away the mystery and superstitution in regard to the cause of syphilis, and classified it into genital and extragenital. This also proved it to be an infectious and contagious disease.

As it took several hundred years to learn that syphilis is a venereal disease, it will probably take many more years before the public will associate it with the contagious diseases, and recognize it as

such.

Although it appears from statistics that only ten per cent, of all cases of syphilis are of nonvenercal origin, I am sure that the number would be much larger if all cases were recognized and reported. The great majority of cases of extragenital syphilis occur through infection from the mouth by the original characteristics of the lips. So, while genital syphilis is due to impure sexual contact, most cases of extractil plant are musted by kissing, or, as in the tractice begins to panted, by assault and battery.

This method of producing syphilis by assault and battery develops a new field of interest, both from a medical and legal point of view. It is of special interest to the general practitioner, who may be called upon to treat wounds received in a fight. He should bear in mind that such wounds are avenues of infection from syphilis, and at the time he should inquire about the general condition and appearance of the other party.

Several years ago, at the New York Hospital, there occurred a very unusual case bearing on this

point.

A young man, thirty-three years of age, printer by trade, had a fight with another man three weeks previous. He came for treatment of a greatly inflamed ear. The sore ear had been irritated by different applications, and when first seen the entire left auricle was greatly inflamed and there was a crusted exudation around a large ulcerated surface. Diagnosis of dermatitis was made.

Some weeks later the diagnosis was changed to chancre of ear, as the patient had mucous patches and other definite

syphilitic signs.

It was learned that the man with whom he had fought had early syphilis, and his mouth was sore from mucous patches. Thus it was evident that syphilis was communicated by biting in assault and battery, and that the infection came from the mucous patches in the mouth of the other party.

The two cases following came under my observation and continued with treatment until apparently cured—taking a regular three year scientific course leading to the degree A. C.—apparently cured; no diploma, however, was given:

Case I.—The first was a policeman on the force in this city, who unfortunately got into a fight with a bum and, in protecting himself, struck his antagonist in the mouth, a very unwise thing for any one to do. An infected wound on the back of the hand resulted; the wound did not heal as it should have done, and later on the usual signs of syphilis began to appear. The point of interest to note is that the sore on the back of the hand was not characteristic of a chancre at all, but the epitrochear glands of the elbow of that arm were very much enlarged, one being of the size of a marble, and remained so until vigorous treatment for syphilis was begun.

Enlargement of the lymphatic glands in the region of the primary infection is one of the most constant as well as important of all symptoms of syphilitic infection. Fournier found this enlargement absent in only three cases out of 265 men, and three out of 233 women. Hutchinson has twice seen chancres in policemen who have become wounded in scuffles with infected men.

At the museum of the Hôpital St.-Louis there is a model of a hand with chancre. 'Lesage's monograph, Chancre par morsure, refers to a case of chancre of a finger of a policeman from a bite.

Case II.—The second case was still more unusual and more interesting, as this was a case of chancre of the scalp.

aThis occurred in a man thirty-five years of age and a statement came to me with a scalp wound received in a fight, being bitten by his antagonist two months previous. He had treated the wound in his scalp, but it did not heal. When he consulted me he had this wound in the scalp and a papular eruption of syphilis. The sore in his scalp was in the parietal region, right side, irregular in outline, about one inch in diameter, and covered by a scab. When the scal was removed pus oozed out, and the wound bled easily. Hair had fallen out around the wound area, size of half and the The unrigular glauds on both sides were much enlarged. On the right side especially there were also three enlarged cervical glands, on the size of a cherry.

There was no other sign of entry of injection, and he had no illist intercours. A diagnosis of chance of the

scalp and a papular crupton of syphilis was made. He responded promptly to antisyphilitic treatment, the wound healed and his hair returned.

Both of these cases were infected from nuccus patches, being bitten by their antagonists in assault and battery. So, you see, it is not safe to hit a man in the mouth nor to be bitten by a two legged animal.

Rollet states that on several occasions he has known syphilis to be purposely communicated through biting, the person actuated by malice and desiring to give syphilis to the other.

From a legal point of view, these cases are of great interest. That a person may be legally held liable for communicating syphilis, either wilfully or

Case II. Clouder of the scale

carelessly, is shown by cases occurring in the literature of foreign countries. Such cases have also been decided in this country, both in the Court of Appeals in Kentucky and the Supreme Court of North Carolina.

Bulkley states that one of his patients received \$5,000 from a man who infected her with syphilis, although the case didn't come to court, it was settled through legal counsel. There is also reported that most remarkable case of cases:

A midwife with chancre of the finger infected four-teen women during their confinement. Eight husbands of these women became infected through intercourse, and the fine figure for field model. Here we have a total of thirty-one persons innocently infected through the criminal negligence of a midwife with chancre of the finger.

This woman knew she had a chancre of the finger and was being treated for it. She was tried and convicted of communicating syphilis; she was fined and also sentenced to two years' imprisonment.

So these two interesting cases of mine here reported, these two cases of syphilis communicated in assault and battery, are of interest both from a medical and from a legal point of view.

DIES CANICLIARES

"Dog Days": "The Physitians Vacation."

By John Knott, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc.,

(Concluded from page 162.)

I have already referred to the testimonies of ancient classic writers, prose and poetical, to the—very evidently—general practice of increased imbibition at this particular season. As the sagely philosophic Latin poet advised his readers:

Dum sentis latrare canem, rugire leonem Te medicus curet Bacchus, et umbra tegat.

And the very fact of the continuous presence of an elevated atmospheric temperature—the highest of the annual cycle—and the thirst (however innocent) which necessarily accompanied the same, would argue pretty convincingly, even to the nonprofessional mind, against the artificial withdrawal of fluids from the human economy by the exhibition of hydragogue cathartics, or the practice of venesection, or the making of issues on the cutaneous surface

Sir Thomas Browne then proceeded to examine, with judiciously critical care, the other various aspects in which the noted aphorism of Hippocrates may be viewed, and the possible sources of its original inspiration and subsequent development:

The second testimony is taken out of the last peece of his Age, and after the experience (as some thinke) of no lesse than an hundred years, and that is his booke of Aphorismes, or short and definitive determinations in Physicke; the Aphorisme alleadged is this, sub Cane & anticane, can substitute the Aphorisme alleadged is this, sub Cane & Anticane, say some, including both the Dogstarres, but that cannot consist with the Greek ἐπὸ κυνὰ καὶ πρὸ κυνός, nor had that Criticisme been ever omitted by Galen; now how true this sentence was in the mouth of Hippocrates, and with what restraint it must be understood, will readily appeare from the difference between us in circumstantiall relations.

And first concerning his time and Chronologic, he lived in the reigne of Artaxerxes Longimanus about the 82. Olympiade, 450, yeares before Christ, and from our times above two thousand. Now since that time (as wee have already declared) the Starres have varied their longitudes, and having made large progresions from West to East, the time of the Dogstars ascent must also very much alter; for it ariseth later now in the yeare, then it formerly did in the same latitude, and far later unto us who have a greater elevation; for in the dayes of Hippocrates this Starre ascended in Cancer which now ariseth in Leo, and will in progression of time arise in Virgo; and therefore in regard of the time wherein he lived, the Aphorisme was more considerable in his dayes then it is to us, or unto his country in

The place of his nativity was Coos, an Island in the Myrtoan Sea, not far from Rhodes, described in Mappes by the name of Lango, and called by the Turks who are masters thereof Stancora, according unto Ptolomie of Northern latitude 36, degrees; that he lived and writ in these parts, is not improbably collected from the Epistles that passed betwirk him and Artaxerxes, as also between the Citizens of Abdera, and Coos, in the behalfe of Democritus; which place being seated from our latitude of 52, 16 degrees Southward, there will arise a different consideration, and we may much deceive our selves if we conforme the ascent of Starres in one place unto another, or conceive

they arise the same day of the moneth in Coos and in England; for as Petavius computes in the first Julian yeare, at Alexandria of latitude 31. the Starre arose cosmically in the twelfth degree of Cancer, Heliacally the 26. by the compute of Geminus about this time at Rhodes of latitude 37. it ascended cosmically the 16 of Cancer, Heliacally the first of Leo; and about that time at Rome of latitude 42. cosmically the 22. of Cancer and Heliacally the first of Leo, for unto places of greater latitude it ariseth ever later, so that in some latitudes the cosmicall ascent happeneth not before the twentieth degree of Virgo, ten dayes before the Autumnall Æquinox, and if they compute Heliacally after it in Livis

Againe, should we allow all, and only compute unto the latitude of Coos, yet would it not impose a totall omission of Physicke; for if in the hottest season of that clime, all Physicke were to be declined, then surely in many other, none were to be used at any time whatsoever; for unto many parts, not only in the Spring and Autumne, but also in the Winter the Sun is nearer, then unto the clime of

Coos in the Summer.

Having thus dealt with the chronological and astronomical aspects of the association of the dog star with an annual temporary subsidence of medical and surgical activity—in a tone and manner distinctly demonstrative of the extreme care and attention which he had bestowed on the subject, and the broad mental capacity and high intellectual attainments which he had brought to bear on the matter so chosen for critical discussion—our author proceeds to the consideration of its purely therapeutic relations:

The third consideration concerneth purging medicines, which are at present far different from those implyed in this Aphorisme, and such as were commonly used by Hippocrates; for three degrees wee make of purgative medicines: the first thereof is very benigne, nor far removed from the nature of Aliment, into which upon defect of working, it is oft times converted, and in this forme do we account Manna, Cassia, Tamarindes and many more, whereof we finde no mention in Hippocrates: the second is also gentle, having a familiarity with some humor, into which it is but converted if it faile of its operation; of this sort are Aloe, Rhabarbe, Senna, &c. whereof also few or none were knowne unto Hippocrates; The third is of a violent and venemous quality, which frustrate of its action, assumes as it were the nature of poyson, such as are Scammoneum, Colocynthis, Elaterium, Euphorbium, Tithy-mallus, Laureola, Peplum, &c. of this sort it is manifest Hippocrates made use, even in Fevers, Pleurisies and Quinsies; and that composition is very remarkable which is ascribed unto Diogenes in Ætius, that is of Pepper, Sal Armoniac, Euphorbium, of each an ounce; the Dosis whereof foure scruples and an half, which whosoever should take, would finde in his bowells more then a canicular heat though in the depth of winter; many of the like nature may be observed in Ætius Tetrab. 1. Serm. 3. or in the book De Dinamidiis, ascribed unto Galen, which is the same verbatim with the other.

Now in regard of the second, and especially the first depree of Purgatives, the Aphorisme is not of force, but we may safely use them, they being benigne and of innoxious qualities; and therefore Lucas Gauricus, who hath endeavored with many testimonies to advance this consideration, at length concedeth that lentitive Physicke may bee used, especially when the Moone is well affected in Cancer or in the watery signes; but in regard of the third degree the Aphorisme is considerable; purgations may be dangerous, and a memorable example there is in the medicall Epistles of Crucius, of a Roman Prince that dyed upon an cunce of Diaphænicon, taken in this season; from the use whereof we refraine not only it hot seasons, but warily exhibit it at all times in hot diseases, which when necessity requires we can performe more safely then the Ancients, as having better wayes of preparation and correction; that is, not only by addition of other bodyes, but separation of

noxious parts from their own,

This information regarding the methods and means of purgation which were employed in the classic ages, by the most cultured and artistic people in the world, and which found favor in the eyes of the great "father of medicine" himself, offers some consolatory evidence of our improvement, in some directions at least, on the violent—and often, it must be feared, destructive—clinical therapeutics of that philosophic (and so ofter supersubtle) nation, in the brightest period of its extraordinary introspective wisdom. If we have, in breathing the corrupt atmosphere of a grossly materialistic age, so far sinned as to come short in an immeasurable degree of the glory of this luminous quality of the Grecian sages, we have made some crude compensation in the direction of medical chemistry and the sympathetic treatment of the victims of injury and disease.

The great physician of the metropolitan mother of "parchment" gave a meteorological explanation

of the influence of the canicular period:

And although Astrologie may here put in, and plead the secret influence of this Starre; yet Galen I perceive in his Comment, makes no such consideration, confirming the truth of this Aphorisme from the heat of the yeare, and the operation of Medicines exhibited, in regard to that bodies being heated by the Summer, cannot so well endure the acrimony of purging Medicines, and because upon purgations contrary motions ensue, the heat of 'the Ayre attracting the humours outward, and the action of the Medicine retracting the same inward: but these are readily salved in the distinctions before alleadged, and particularly in the constitution of our climate and divers others, wherein the Ayre makes no such exhaustion of spirits; and in the benignity of our Medicines, whereof some in their owne natures, others well prepared, agitate not the humours, or make a sensible perturbation.

And this very sensible (and very philosophic, and very learned) physician proceeds to a judicial summary of the tangible knowledge at which his researches had led him to arrive in this inquiry. And a very remarkable disquisition the whole is—for an author at the age of forty-one, who had been busily engaged in practice during the previous twenty years:

Nor do we hereby reject or condemne a sober and regulated Astrology; we hold there is more truth therein then in Astrologers, in some more then many allow, yet in none so much as some pretend; we deny not the influence of the Stars, but often suspect the due application thereof; for though we should affirme that all things were in all things, that heaven were but earth celestified, and earth but heaven terrestrified, or that each part above had an influence upon its devided affinity below; yet how to single out these relations, and duely to apply their actions is a worke oft times to be effected by some revelation, and Cabala from aboue. rather then any Philosophy, or speculation here below; what power soeuer they haue upon our bodies, it is not requisite they should destroy our reasons, that is, to make us rely on the strength of Nature, when she is least able to relieve us, and when we conceive the heaven against us, to refuse the assistance of the earth created for us; this were to suffer, from the mouth of the Dog above, what others do from the teeth of Dogs below; that is, to be afraid of their proper remedy, and refuse to approach any water, though that hath often proved a cure unto their disease. There is in wise men a power beyond the Stars; and Ptolomy encourageth us, that by fore-knowledge, wee may evade their actions; for, being but universall causes, they are determined by particular agents, which being inclined not constrained, containe within themselves the casting act, and a power to command the conclusion.

In his vast storehouse of the facts and opinions of the inextricable science and superstition of those classic ages which we are wont to call ancient, we find the elder Pliny ever returning, again and again, to the subject of dogs and their ways—and their madness; also to the dog star and its associations and its influences, and to human hydrophobia and the ways and means available for its prevention and its cure. The topic was evidently one which was evermore in receipt of perennial attention. In one of those very numerous allusions we learn that:

The biting of mad dogs are most dangerous to a man, as we haue said before, especially during the dog-daies, while the dog-star Syrius is so hot, for they that are so bitten, lightly are afraid of water, which is a deadly signe. To preuent therefore that dogs fall not mad, it is good for thirtie or fortie daies space to mingle hens or pullins dung specially with their meat: againe, of they be growing into that rage, or tainted already, to give them Ellebor with their meat:

The catalogue of his remedies for human hydrophobia is a very comprehensive one, indeed; and the efficacy of many of the therapeutic items found listed therein makes the reader sometimes wonder how it was that any cases were allowed to end fatally—as many were very readily obtainable in almost any locality. One of the first to be commended in this connection is the great Italian panacea:

Garlicke, it is singular good . is of power to dull and kill the force of the venomous herb Aconitum . yea, it conquereth the soporiferous & dedly quality of Henbane: the bitings also of a mad dog it healeth, if it be applied you the hurt or wounded place with him. As for the sting of serpents verily, Garlick is exceeding effective.

And this fertile generator of malodorous gastropulmonary effluvia retained the same—with very many another—item of therapeutic reputation down into the eighteenth century (if not later); for we find William Salmon, of unsurpassed herbal attainments, assuring his readers that it "helps the biting of all Venomous beasts, inwardly taken, and outwardly applied."

The next antihydrophobic agent that I have noted on Pliny's list is:

Colewort . . . Epicharmus is of opinion, That for the biting of a mad dog, a man need doe no more but lay to the sore a cataplasme of this herbe alone: but surer it were saith he and more effectual, if Laser and strong sharp vinigre were ioyned thereto. He addeth moreouer and saith, that if it be giuen to dogs with some piece of flesh it will kill them.

Some other herbal remedies are recommended which do not appear to have secured a niche in the temple of therapeutic fame:

The Plants called Bulbs, being applied in form of a liniment . . with honey it cureth the biting of mad dogs: howbeit Eratosthenes taketh pitch in stead of honey

for the said purpose.

Alisanders, which the Greeks terme Hipposelinum is a good counterpoison against the biting of Scorpions.

Taken in drinke, or applied as a liniment, it healeth the biting of a mad dog.

The reputation of *rue* displays the tenacity of its existence on the page of William Salmon, who avers that "it excels all manner of poison, helps the biting of mad dogs, stinging of Serpents, and wounds made by other Venomous beasts." Of this famous *simple*, Pliny informs us:

Rue is an herb as medicinable as the best. . . . It is singular good against the stinging of Serpents: for the very Weasels when they prepare themselues to combat with them, vse to eat this hearbe before-hand for to be secure from their Venome. Auailable it is also against the pricks of Scorpions and Hardi-shrewes, against the stings of Bees, hornets, and wasps, against the poison of the Cantharides and Salamanders, yea and the biting of a mad dogge; if it be vesed in this wise, namely to take a saucer full or acctable of the juice and so drink it with wine: also to stamp or champ in the mouth the leaues thereof, and so lay them ypon the grieued place with honey and salt; or else to seeth them with vinegre and pitch. Folke say moreouer, that whosoeuer is wel rubbed with the juice of Rue, or otherwise but cary it about him, shal be sure ynough

for being either pricked, stung, or bitten with any of those hurtfull and venomous creatures abouenamed: . . .

And he quotes Castor in favor of the efficacy of horehound:

Also a liniment (saith hee) made of Horehound stamped together with old swines grease, cureth all wounds occasioned by the biting of mad dogs.

And of a certain flower which still continues to exercise the attention of the herald at arms and symbolist, if not of the practical therapeutist, we learn that:

As touching the Flower-de-lis, the red is thought to be better than the white. . . The weight of two drams eaten with bread or drunk with water, resisteth the poison of scorpions. Being made into a liniment with oile, and so applied, it cureth the bitings of mad dogs, and healeth the parts mortified with extreame cold.

The next Plinian remedy for hydrophobia retained its reputation into the eighteenth century:

Touching Baulm, which the Greeks call Melitis or Melissophyllon: . . The juice taken in drinke bringeth women to their ordinary monethly courses: it discusseth ventosities, and healeth vlcers: it allaieth the paines of any gouts, and cureth the biting of mad dogs: . . .

And we are assured by the redoubtable William Salmon that:

It comforts the Stomach, removes Melancholy, cheats [sic] the Heart, causes pleasant Dreams, expels poyson, cures the Plague, Feavers, the biting of Mad Dogs, and all other venemous Creatures; eases the Tormina, helps Palsies, Apoplexies, Epilepsies,

In the sunny climes of the South and East, the fig was always a prominent member of the vegetable kingdom—botanically, dietetically, and therapeutically. So that we are not (or should not be) surprised on learning that:

The tender tops & twigs of fig-tree branches are singular to cure the biting of mad dogs, if they be applied to the skin where it is broken. . . Fig-tree leaues stamped with vineger, do restrain the venom, occasioned by the biting of mad dogs: . . .

As many vertues as the mild fig-tree hath, yet the wild is much more effectuall in operation: howsoeuer she yeeldeth lesse milke or white juice than the other doth. For a branch onely of it, is as good as rennet or rindles to make milk turn and run to a cheese curd. Howbeit, that milky liquor which it hath, if it be gathered and kept vntill it be dry and wax hard, serueth to season our flesh meats, and giue them a good tast. . . . Applied in a liniment with the floure of Feni-greeke, it easeth the pains of the gout: t clenseth the leprosie, and foul wild scab: it killeth ring; worms and fell tettars: it scoureth away freckles and such flecks as disfauor the face: likewise it cureth the parts stung with venomous serpents, or bitten with mad dogs.

The green figs of this wild fig-tree brought into a lini-

The green figs of this wild fig-tree brought into a liniment, do mollifie and discusse the kings cuil, and all other tumors and apostemes. And in some measure the leaues also haue the same operation: Chuse the softest and tenderest of them, let them be stamped and mixed with vineger, they will cure running sailes and sores, ease bloudy fals and chilblanes, yea, and scoure away filthy scurfe or dandruffe. The said green figs, together with the leaues, incorporat with hony, doe cure the wens or exulcerat bunches, which yeeld matter out of them resembling hony: likewise they heal the biting of mad dogs.

The natural powers of Amygdala amara enabled it in the days of Salmon to "help the Strangury, and cleanse the Lungs, cure the Cough, and shortness of breath, and the bitings of mad Dogs." And we learn from Pliny that:

The bitter Almonds . . . cure the angry night-foes, called chilblanes and bloudy-falls: applied with cold wine, they cure vlcers which grow to putrifaction; and with hony, the biting of mad dogs:

The omnipotent antidote of Mithridates necessarily embraced the virus of rabies within the sphere of its powers. So we read that:

After that Mithridates (that most mighty and puissant

king) was vanquished. Cueuus Pompeius found in his secret closet or cabinet, among other precious jewels, the receit of a certain antidote or preservatiue against poison, set down vider the hand of the sayd prince, in a private note-book of remembrances, in this maner following: Take 2 dry walnut kernels, as many figs, of rue, 20 leaues: stamp al these together into one masse, with a graine or corn of salt among. Vider which receit, was thus much subscribed, VVhosoeuer vse to eat of this confection in a morning next his heart, there shall no poison hurt him that day. It is said moreouer, that the kernels of walnuts chewed by a man or woman fasting, doe cure the biting of a mad dog, so that the place be annointed and dressed therewith.

The next couple of items in the antirabic series of simples have permitted their therapeutic interest to evaporate pretty completely, although it must have been copious and inspiring in classic times:

The herb Alysson . . . took that name Alysson, because those that be bitten with a mad dog, if they drink it with vineger, or weare it tied fast about them, shall not likewise run mad. But it is verie strange which is said moreouer of this herb, that the very sight thereof is enough to dry vp and consume that venomous matter or humour infused by the touch of the said dog, and which is the cause of madnesse.

The herb Ampeloprasos growth in vineyards, bearing leaves resembling Porret: but it causeth them to belch soure that eat thereof. Howbeit, of great power it is against the sting of serpents. It prouoketh vrine & women's monthly terms. And yet whether it be drunke or applied outwardly, it is passing good for them that pisse bloud, & represseth the issue & eruption thereof. Our midwives vse to give it vnto women newly delivered and brought to bed: likewise it is found to availe much vnto them that be bitten with mad dogs.

Then our great pagan moralist (as well as natural historian) alights upon an item of supernatural revelation and embraces the opportunity of treating his readers to a very well timed and most appropriate professional homily:

But the most dishonest and shamefull cause why so few simples in comparison be knowne, is the naughtie nature and peevish disposition of those persons who will not teach others their skill, as if themselves should lose for euer that which they imparted vnto their neighbor. Ouer and besides, there is no certain meanes or way to direct vs to the inuention and knowledge of hearbes and their vertues: for if we looke vnto those hearbs which are found already we are for some of them beholden to mere chance & fortrune; and for others (to say a truth)) to the immediat reuelation from God. For proofe hereof, mark but this one instance which I will relate to you. For many a yeare vntille now of late daies, the biting of a mad dog was counted incureable: and looke who were so bitten, they fell into a certain dread & feare of water: neither could they abide to drink, or to heare talk thereof, and then were they thought to be in a desperat case: it fortuned of late that a souldier, one of the gard about the Pretorium was bitten with a mad dog, and his mother saw a vision in her sleep, giuing (as it were) direction vuto her for to send the root vnto her sonne for to drink, of an Eglantine or wild rose (called Cymorrhodon) which the day before she had espied growing in an hortyard, where she took pleasure to behold it. This occurrent fel out in Lacetania, the nearest dier beforesaid vpon his hurt received by the dog, was ready to fall into that symptome of Hydrophobie, and began to feare water: there came a letter from his mother, adueruising him to obey the wil of God and to do according to that which was renealed vnto her by the vision. Whereupon he dranke the root of the said sweet brier or Eglan tine, and not only recoursed himselfe beyond all mens expectation: but also afterward as many as in that case tooke the like receit, found the same remedy.

Between the time, the writer in Physick knew of no medicinable vertue in the Eglantine, but only of the sponge or little ball, growing amid the pricky branches thereof, which being burnt and reduced into ashes, and incorporate with honey into a liniment, maketh haire to come again.

He subsequently returns to this heaven sent rem

edy, and refreshes the mind and memory of the reader:

Moreouer, a mad dog letteth in a dangerous poison by the wound that his tooth maketh, against which there is not a better thing than dog-rose of the Eglantine called Cynorrhodon, as I have before declared.

Then we are treated to a couple of vegetable remedies, whose therapeutic properties were of merely terrestrial invention:

Betonie is likewise good therefore if it be drunk in old wine. Veruain, which the Greeks call Peristerees, is an herb bearing one main stalk of a good heigth, furnished well with leaues, spreading forth toward the head into other branches, nuch sought to by doues and pigeons, whereupon it took the foresaid name Peristereos. They say, whosoeuer carry this herb about them, there dare not a dog bark at them.

Stinking Horehound, which some Greeks call Ballote, others Melamprasion, i. Black Horehound, is an herbe tufted full of branches: the stems be black and cornered; the leaues wherewith they be clad and garnished, are somewhat hairy, resembling those of sweet or white Horehound, but that they be bigger, blacker, and of a stinking sauor: but the leaues stamped and applied with salt, be very effectual against the biting of a mad dog:

The next antirabic item of Pliny's armamentarium suggests some accidental intercrossing of the remotely ancestral germs of homwopathy and of Christian Science:

The haire of yong boy-children which is first clipped off, is held to be a singular remedy for to assuage the painful fits of the gout, if the same be tied fast about the foot that is grieued: & generally their haire, so long as they be vnder I4 yeres of age, easeth the said anguish, if it be applied vnto the place. Likewise, the hair of a mans head cureth the biting of a mad dog, if it be laid to the place with vineger: it healeth also the wounds in the head, applied with oile or wine.

And this next again in order is surely a primordial blend of animal therapeutics with antiseptic surgery:

But surely, euery mans own water (if I may for reuerence of manhood so say) is simply best; and namely, if the Patient that is bitten with a dog, do straightways bath the place therewith; or in case there be any prick of vrchin, hedghog, or such like spill sticking in the flesh, to apply the same thereto in spunges or wooll, and so let it lie on. But say it was a mad dog that bit the Patient, or that he be stung with a Serpent, it is good to temper it with ashes and lay it vnto the sore.

Now, although William Salmon attributes to the excretory fluid derived from the living human kidney a long series of therapeutic virtues, and gives careful directions for the preparation therefrom of an Essentia, a Magisterium, an Oleum, a Spiritus, and also a Sal Urina volatile, he does not prescribe any of these in cases of hydrophobia!

Then we have a couple of genuine specimens of the classic practice of "Animal Therapeutics."

As for the Hyæna. . . . The flesh of this beast eaten, is very effectuall against the biting of a mad dog; and yet the liner is of greater efficacy in this case.

Salmon also assures his readers, under this head, that "The Liver eaten, is good against the biting of a Mad Dog." And, again, Pliny that:

If a man be wounded by the biting of a mad dog, some there be who cut round about the place to the very quicklaying thereto the raw flesh of a calfe, and then gine the patient to drink the broth of the said flesh boiled, or elshogs grease stamped with quick-line. Others highly praise the liner of a buck Goat, affirming that if it be once applied he shall not fall into that symptome of hydrophobie or fearing water, incident to those that be bitten with a mad dog. They commend also a liniment made of goats dung and wine or hony tempered together: like as the decoction of a grey or budget, of a cuckedward as wallow, taken in

And, as we continue to delve in the Plinian mine of Materia Medica, we next strike a very crude example of the prescientific utilization of the healing

properties of lanoline:

The fattie wooll of a sheep being either applied, or put vp in maner of a pessarie, drawes down the dead infant out of the mother's belly: and yet the same otherwise re-presseth the immoderat flux of womens fleurs. If it be couched hard & close within the wound occasioned by the biting of a mad dog, it serueth to great purpose; but with this charge That it be kept bound thereto & not remoued vntill the seuenth day be past: . [Howbeit, note this, that the wooll growing vpon the sheeps neck is euer best and most medicinable: and if we regard the country from whence it coms, that of Galatia, Tarentum, Attica, and Miletum, is alwaies reputed better than any other.]

Our next quotation presents a somewhat complex (and perplexed) blend of animal therapeutics with cure by homoepathic remedy and prevention by amulet precaution-with a specially aromatic spice of

homeopathic prophylaxis:

For the biting of a mad dog take the ashes of a dogs head burnt, and apply it to the sore, it wil saue the Patient from the symptome of being afraid of water; which is incident to such as be so bitten. [And now by occasion of speech know thus much once for all, That all things which are to be calcined require one and the same manner of burning, that is to say, within a new earthen pot neuer occupied before, well luted ouer with strong cley, and so set into an ouen or furnace vntill such time as the contents be calcined.] The said ashes made of a Dogs head is singular good likewise to be drunke in the same case: wherefore some haue giuen counsell to eat also a dogs head. seeke after the wormes that breed in the carkasse of a dead dog, and hang the same fast about the necke or arme of the party that is bitten: or els they lap within a cloath some of the menstrual bloud of a woman, and put it vnder the cup or pots bottome out of which the patient drinketh. And there be some againe who burn the haires of the same mad dogs taile, and conueigh the ashes handsomely in some tent of lint into the wound. Moreouer it is commonly said, That as many as haue a Dogges head about them, no other Doggs will come neere to do them any harme. In like manner, if a man carry a dogs tongue in his Shooe vnder his great toe, there will no Dogges bay or bark at him. If hee haue about him a weazils taile, which hath beene let goe againe after it was cut away. There is to be found under the tongue of a mad dog, a certaine slimy and grosse spittle, which being given in drinks to those that are bitten, keep them from the feare of water; which symptome the Greeks call Hydrophobia: but the best and most soveraigne remedy of all other, is the liver of the same dog that in his madnesse bit any body, eaten raw, if possibly it may be; if not, yet sodden or boiled any way; or else to cause the Patient for to sup the broth that is made of the same dogs flesh. There is a certaine little worme in dogs tongues, called by a Greeke name Lytta, which if it be taken out when they be young whelps, they will never after proue mad, nor lose their appetite to meat. The same worme giuen to such as are bitten with a mad dog, prescrueth them from being mad; but with this charge, that before they take the same, it must be carried three times about the fire. Also the braines of a Cocke, Capon, or Hen is singular good against the biting of a mad dog: but if one haue eaten the same, the vertue thereof indureth but for that yeare onely, and no longer. It is commonly said that the crest or combe of a Cocke well bruised and stamped, and so laid in manner of a cataplasme to the place bitten, is very effectuall to cure it: as also the grease of a goose incorporate with Furthermore, some there be who vse to sait the honey. Furthermore, some there be who vie to salt the flesh of dogs which haue bin mad, and so keepe it to giue in meat vinto those who chance to be bitten by others. There be who take some young whelpes, male or female according to the sex of dog or bitch that hath bitten any one, and presently drowne them in water causing the Patient to eat their liuers raw. The yellow or reddish dong of a cock or a hen, dissolued in vineger, and applied to the sore, is singular good. The ashes also of an hardy-shrewes that the provided alwaise that the shrew were let greatly an area of the sore in the shrew were let greatly and the shrew were let greatly an taile; provided alwaies, that the shrew were let go aliue, so soone as she was cart-tailed. Moreouer, a piece of clay taken from a swallows nest, made into a liniment with vineger: or the ashes of young swallows newly hatched

and burnt: the old skin also or slough which a snake vseth to cast off in the spring time, stamped with a male crabfish, and with wine brought into a Cataplasme, be all especiall remedies for the biting of a mad dog. As for the skinne or spoile of a snake, if it be put alone in a chist, presse, or wardrobe, among cloaths, it will kil the moth. But to come again vnto a mad dog; his poison is so strong. that whose uer do but tread vpon his vrine, especially if they have any sore or vlcer about them, they shall sensibly feele hurt thereby. Now what remedy is there for such? None better than the dung of a caple, well wet and tem-pered with vineger, and the same laid very hot within a fig to the foresaid sore.

Some valuable antirabic preparations were elaborated (cooked) from the tissues of certain deni-

zens of the ocean depths and borders:

The other sauce, Alex, is come to be made of Oisters, sea Vrchins, sea Nettles, Crabfishes, Lobstars, and the liners of sea Barbles. The grosse liquor or sauce Alex, healeth the scab in sheep, if the skin be scarified or skiced, and the same Alex poured therupon. Also it is singular against the biting of a mad dog, or the prick of As for Garum, it healeth any sea dragon: fresh burne, if a man drop it vpon the place, without naming it, or saying that it is Garum: good it is besides for the biting of mad dogs, but especially for the Crocodiles

Animal, vegetable, and mineral products were sometimes combined in the preparation of a single remedial application; as in the following example:

A liniment made of nitre and fullers earth, of each a like weight, incorporat with vineger, taketh away the foule morphew, if the skin be annointed therwith: mixed with rosin, or with raisons of white grapes stamped stones and all, it draweth uncoms and fellons to an head, and breaks them: reduced into an ointment with swines grease, it preserueth the genitoirs from inflammation, & cureth them: good likewise for the measils and small pocks which break out in all parts of the body: put rosin thereto, and incorporat them both in a liniment with vineger, it healeth the biting of a mad dog, so it be taken betimes at the beginning; and in this manner it cureth also the sores occasioned by the sting of serpents,

Some comparatively simple "preps." were also derivable from the bodies of the denizens of the waters:

Sprots salted haue a special propertie to heal the biting of the beetle or venomous fly. Prester: also in case a man be bitten with a mad dog, it is very good to lay salt fish vnto the sore; yea although the wound were not cauterised with a red hot iron, nor the patients body emptied by a clystre, this cataplasm alone of salt fish is thought sufficient to cure it: the same soked in vineger serues also to be laid vnto the place that is hurt with a sea dragon. Of the same operation and effect is a square piece or canton of the fish Tuny salted and condited.

Limpins also, as well as Burrets. . . . As touching the flesh that they haue, it serueth in a cataplasm to be laid vnto the biting of mad dogs.

And the last remedy which I have found in the long antirabic series of that wonderful classic compiler is more nearly related to modern practice than most of those items:

An actuall cauterie of yron red hot, cureth many diseases, and especially the biting of a mad dog: in which case it is so effectuall, that if the poison inflicted by that wound, haue preuailed so far, that the patient be fallen into an Hydrophobie thereby, and cannot abide drinke or water, let the sore be seared therewith, the party shall find help presently.

And so let this subject, formerly so direful, now pass-not, however, without a parting blessing on the memory of Pasteur, and a momentary thanks offering to our beloved (still, happily, surviving) octogenarian Lister; followed by a copious apology to the reader, whose patience I must have seemed to him to have set myself deliberately to exhaust. But

210

the dog day heat must form my excuse; and every returned physician will, I trust, find himself as a giant refreshed by his term of holiday repose-after perfect enjoyment of the full period of the "vacation" prescribed for him by his great exemplar, the inspired "father of medicine" himself. And thus the seasons come and go, the dog star fulfills its annual engagement of visibility on the celestial stage; the creative sun functions as the divine agent in the furnishing of illuminating light and refreshing heat, as in associated promotion of life and growth and reproduction-vegetable and animal. The spheres still revolve-apparently-as they did in the days of old, with, of course, all respectful deference to the necessities of precession and nutation. And Apollo, as solar deity, is still found to wield the guiding wand of the celestial orchestra; while the nine inspired and inspiring Muses are his appointed agents in the continuous mathematical regulation and musical attunement of the concerted movements of revolution, each of her own sphere, and the maintenance of the uninterrupted harmony of the resultant auditory-ethereal-undulations which are sensible only to angelic ears. The supreme master hand still guides and governs and harmonizes all; while man's loftiest aim and sublimest ambition is to be one day rewarded by election to permanent membership of that spiritual audience which is privileged eternally to enjoy the ineffable bliss produced by the music of the celestial spheres. So thought the devout Pythagorean of old, and Professor Kennedy Duncan has somewhere introduced this notion in characteristically happy illustration of latter day "radiant" science, and with a lucidity of view and familiar lightness of touch which prove that the most advanced and illuminating mastery of the "new knowledge" is by no means incompatible with an inspiring appreciation of the esoteric conceptions of the old philosophy. And still, in presence of x rays and n rays-and even the colossal innovation of the Assouan damthe Nile pours forth its annual tribute of irrigating water and fertilizing mud over the land of Egypt; a phenomenon which inspired the divine dictation of Moses and of Isaiah, as well as suggesting some of the weirdly mystical conceptions of the Sibylline oracles, and the profound symbolism of the "golden verses" of Pythagoras. But the concepts of the "New Knowledge" have necessarily broken up the poetical fabric of the old; and after successful plowing up of the spheres, and splintering of the atoms, we are now plunged in the mire of the "electron theory"! Still, we exist in the hope that even its muddy atmosphere will in process of time become clarified—by autoillumination of its own radiations (?). Anyway, our planet has long ago been displaced from the position of central rest accorded to it by the soporific influence of mediæval doctrine, and whirled into a course of active duty on its definite annual pilgrimage through the realms of space. Eppur si muove!-and sometimes as the evening star appears above the brim of the broad Atlantic, and emits its twinkling reflections from the calm surface of its darkening briny azure mirror, we catch ourselves muttering, half unconsciously, the vaguely unsatisfied (and dreamily hankering) query, "Does it really?"

THE SOLVENT ACTION OF THE SULPHOCY-ANATES UPON THE LIME AND MAGNESIUM DEPOSITS IN THE SYSTEM.

BY WILLIAM BENTLEY, M. D., Athens, O., Professor of Chemistry, Ohio University, Athens, O., AND BERNARD R. LEROY, M. D., Athens, O.

The interesting fact, brought to light by my study of the saliva (1), that there is always a precipitation of the calcium and magnesium, held in solution in normal saliva, by the increased content of ammonia and a simultaneous decrease or entire absence of the sulphocyanates caused me to make a study of these substances, which I hope will be of interest.

First was noticed that when the saliva was normal the basic salt was one of potassium, ammonium, and the sulphocyanates in small and about equal quantities, the lime and magnesium present held in perfect solution, but that in all cases of departure from the line of health was noticed deposits of more or less of the lime salts in and around the teeth, this condition could, in a measure, be remedied by the administered medicinal dose of sodium sulphocyanate (which is of all the sulphocyanates the least poisonous to man), this fact led me to use it in cases of arteriosclerosis in small doses, giving prompt and rapid relief to the patient, and in time producing an improved condition which I attributed to the direct action of the sulphocyanate upon the deposited salts of lime. Again did this lead to experiments in the laboratory, which again led to the further study of this interesting subject by Dr. Bentley, who is making an exhaustive study of the question of the solvency of lime and magnesium calculi.

The doctor kindly granted me permission to make use of part of his findings, to better elucidate that which is but very little understood at the present day, the action of the "ion" in extreme dilution.

It is now some years since I first made use of the sulphocyanates in arteriosclerosis, and in fact in all cases where I had found a high blood pressure, in all these cases this remedy, a sodium sulphocyanate, acted as by a miracle, so rapid and prompt was it in its action and relief of the sufferer, and it was not until I had about finished a course in the laboratory of hygiene of the University of Pennsylvania did I learn that this drug had been experimented with in this disease by a German scientist, Dr. Pauli (2), who published the results of his experiments, so to him must go the honor of the introduction of one of the best and safest agents that can possibly be used in these conditions.

The drug is given in dilution, and Pauli says that he has given as much as one gramme daily, but I have never found occasion to give more than one grain at a dose, and more often never more than a fraction of a grain well diluted, and this dose given as the symptoms may demand.

From arteriosclerosis to renal calculi is not a far jump, especially in this section of the country, where the potable water comes from a lime magnesium deposit with a free deposit of salt underlying the surface, causing the water to contain much lime, magnesium, and a large content of the chlorides. As would be reasonable to conjecture, the inhabitants

of this section suffer very much indeed from calcarious deposits, and renal calculi are common.

August 1, 1908.]

In analyzing a renal calculus obtained from one of my patients I was surprised to learn that it was composed of calcium carbonate, 60 per cent.; cestimated); calcium phosphate, 25 per cent.; and magnesium phosphate, 15 per cent.; and free from any other contamination. The calculi were of a light colored stratum overlaying one of dark or nearly black color, porous, hard, and very rough edged, as if broken from a larger piece; it is with a part of this stone that Dr. Bentley commenced his study of the solvent power of the sulphocyanates.

It will be noticed further that calculi of this composition have been considered quite rare, the authors on urinanalysis devoting but a few lines to the consideration of this form of calculi, and that from our experiments with the sulphocyanates in arteriosclerosis and the experiments of Dr Bentley, it is safe to say that in this drug we have a remedy which will not only slowly dissolve the already formed stone, but will prevent the formation of the calculi, or other deposit in the system when the sulphocyanides are present in sufficient quantities. It is well worthy of further study.

I will now give in part the results of Dr. Bentley's study of the solvent power of the sulphocyanates on the calculus spoken of before; it will be noticed that the power to dissolve the calculus increases with the dilution up to a certain point, well within physiological limits; and should the sulphocyanates be absent or present in reduced quantities in the system, the administered amount of the sodium salt would not be required to exceed the minimum dose, thereby rendering it much more safe to give for a prolonged length of time.

One word of caution to those who wish to try this remedy. Do not give the sulphocyanates for any length of time, nor in large doses without carefully watching the patient and making repeated measurements of the blood pressure with the sphygmomanometer, and keep an accurate record of the case; in this you will learn that large doses of the drug will not be called for, nor will you give them when you will have learned with what ease small doses will do the work.

Laboratory Experiments.—The purpose of the experiments here recorded was to ascertain the loss experienced by two small renal calculi when digested with dilute solutions of potassium sulphocyanate. The calculi were composed largely of calcium carbonate, but contained also phosphates and salts of magnesium. The potassium sulphocyanate used was chemically pure crystallized salt of the market, and was dissolved in distilled water which had been previously boiled to remove any carbon dioxide which it might otherwise have contained.

The calculi were prepared by washing thoroughly and drying for one half hour in a steam oven. In the first experiment they were digested at ordinary temperature with 50 c.c. boiled distilled water seventy-three and one half hours, after which time they were dried as before and weighed, but no loss was found. Weight of calculi before treatment, 0.0203 gramme; weight of calculi after treatment, 0.0204 gramme.

They were then digested at ordinary temperature with 150 c.c. of a 1 in 30,000 potassium sulphocy-

anate solution ninety-five and one half hours, which produced a slight loss of weight. Weight of calculi after treatment with potassium sulphocyanate solution, 0.0202 gramme.

The experiment was repeated, using a fresh solution of potassium sulphocyanate 150 c.c. as before. but the digestion was made at 37° C. and lasted sixty-six and one half hours. After washing and drying, as before, the calculi showed a decided loss of weight: Weight of calculi before digestion, as above, 0.0202 gramme; weight of calculi after digestion, 0.0196 gramme. Loss 0.0006 gramme, or 2.97 per cent.

Thinking that the loss might be due to the solvent action of water at the higher temperature, the calculi were again digested with water at 37° C. for sixty-six and one half hours, but showed no loss. Weight of calculi before treatment, as above, 0.0196 gramme; weight of calculi after treatment, 0.0196 gramme.

The digestion was repeated exactly as before, except that a I in 6,667 solution of potassium sulphocyanate replaced the I in 30,000 solution and a longer time was employed. Weight of calculi before treatment, as above, 0.0196 gramme; after treatment, 0.0190 gramme; loss, 0.0006 gramme, or

3.06 per cent.

The effect of a I in I,000 solution was next tested, and an attempt was made to determine the time necessary to accomplish the limit of solution. The same amount of solution and same temperature were employed as before, and twenty-four hours were used in the first test. The result was no loss of weight. Weight of calculi before treatment, as above, 0.0190 gramme; after treatment, 0.0190.

The treatment was repeated exactly for another twenty-four hour period with the apparent loss of 0.0001 gramme. Weight before treatment, as above, 0.0190 gramme; after treatment, 0.0189 gramme.

The same solution was used again, but the treatment was extended to sixty-six hours, when there was found a loss of 0.0003 gramme. Weight before treatment, as above, 0.0180 gramme; after treatment, 0.0186 gramme. Entire loss in I in 1,000

solution, 0.0004, or 2.10 per cent.

Very little was learned as to the time factor, but these experiments seem to show that the effect of the stronger solution, I in 1,000, is decidedly less than that of the weaker ones, I in 30,000 or I in 6,667. It seemed possible that the soluble constituent had been removed by previous treatment, and this would explain the apparent smaller efficiency of the stronger solution. Accordingly a fresh I in 30,000 solution was made and the calculi treated in 150 c.c. of it four times. The duration of the first treatment was twenty-four hours, the second twenty-four hours, the third twenty-four and one half hours, and the fourth forty-eight hours. Weight before treatment, as above, 0.0186 gramme; after twenty-four hours' treatment, 0.0183 gramme; loss, 0.0003 gramme; after second twenty-four hours, forty-eight hours in all, 0.0182 gramme; loss. 0.0001 gramme; after twenty-four and one half hours, seventy-two and one half hours in all, 0.0180 gramme; loss, 0.0002 gramme; after forty-eight hours, 120 $\frac{1}{2}$ hours in all, 0.0180 gramme; loss. 0.0000 gramme. Total loss, 0.0006 gramme, or 3.23 per cent.

Thus the absolute loss was the same as before in the same strength of solution. On account of loss of weight in the calculi, the percentage loss was greater, but the absolute and not the percentage loss is significant in this connection, because the amount of solvent is limited, while the amount of substance to be dissolved is in great excess. Regarding the period necessary for complete action we learn that anything over seventy-two and one half hours is unnecessary, but we must have over forty-eight hours' treatment. In the first experiment the same loss was noted in sixty-six and one half hours, and therefore that is sufficient for maximum effect. The period of treatment is therefore between forty-eight and sixty-six and one half hours for maximum loss.

Finally, a solution I in 40,000 was employed, temperature of digestion and volume of solvent same as before, and the time was through inadvertence four days (ninety-nine and one quarter hours). The loss was greater than any time before: Weight before treatment, as above, 0.0180 gramme; after treatment, 0.0173; loss, 0.0007 gramme, or 3.89 per cent.

This dilution was so great that it was thought hardly worth while to carry on experiments with

higher dilutions.

IMPETIGO CONTAGIOSA.

By R. T. Sutton, M. D., Kansas City, Mo.,

First Assistant in Dermatology, University Medical College.

Impetigo contagiosa is an acute, infectious, inflammatory disease of the skin, characterized by the occurrence of superficial vesicles, which quickly dry up and form thin, flat, yellowish crusts. It is one of the commonest of cutaneous affections.

The regions most frequently attacked are the face, hands, and scalp. Commencing as a tiny blister on a very slightly inflamed base, the individual lesion early manifests a tendency to central depression and peripheral extension. Neighboring vesicles frequently coalesce and form irregular patches or circinate groups.

If the rather fragile overlying membrane is broken and the serous or seropurulent fluid allowed to escape, a raw, bright red, moisture exuding surface is exposed. The duration of a lesion is short,

from four to ten days.

The thin, loosely adherent, golden crusts curl up at the margins, and, although itching is slight, seem to possess an almost irresistible attraction for the finger nails of the patient. After a few days they drop off, leaving hyperæmic spots to mark their former sites for a considerable time. The disease is most often seen in young children, especially the unclean and poorly sheltered and fed. In grown persons it frequently results from the infection of slight abrasions, such as those following cold sores, razor scratches, and the self inflicted excoriations in parasitic and other pruritic affections. It is par-

ticularly obstinate and troublesome when it occurs on the faces of men who have a thick stubble of heavy beard. The ætiological cocci, while much nearer the surface than in sycosis, penetrate into the skin crevices a sufficient depth to render their dislodgment and destruction exceedingly difficult at times.

The affection is both inoculable and autoinoculable, and is directly due to the action, single or conjoint, of the Staphylococcus pyogenes aureus and albus, or occasionally, the Streptococcus pyogenes. Infection takes place in the outer layers of the skin, the resulting inflammation usually being confined to the epidermis, seldom extending to the papillary stratum. Because of this superficial involvement there is no scarring.

It is to be distinguished from pustular eczema, varicella, ecthyma, sycosis, the ulcerating syphilide,

and pemphigus.

In pustular eczema we have a preexisting dermatitis with its characteristic symptoms—intense itching, with thickening of the skin and the involvement of a considerable area surrounding the individual pustules.

The lesions of chickenpox are widely disseminated and are much smaller and more uniform than those seen in impetigo. Patches are seldom formed, while the large, thin, flat, flaky crusts are absent. There is usually some associated constitutional disturbance, and the disease pursues a regular, definite course.

The pustules of ecthyma are surrounded by well marked inflammatory areolæ and have thick, tough crusts, which cover more or less ulcerated bases. The disease occurs more frequently in grown persons than in children, and the covered parts, especially the legs, are attacked oftener than the face and hands.

Sycosis seldom gives rise to a mistake. The deep seated nodules, pierced by pus distended hair follicles, from which the shafts can be readily extracted, together with the very considerable amount of inflammation commonly present, render distinction comparatively easy.

The ulcerating syphilide is distinguished by its

slow progress and invariable scarring.

True pemphigus is rare. The vesicles develop suddenly on uninjured surfaces, there is slight if any surrounding inflammation, and the lesions are large (seemingly full grown) from the very first. The contents of the bullæ are more often clear and sterile than mucopurulent in character, and, owing to the noninfectious nature of the disease, only one person in the family is affected.

Few skin diseases yield more readily to proper treatment than impetigo contagiosa. In order to secure the best and quickest results, the crusts must first be removed, otherwise they serve to protect and aid the infecting bacteria by shutting off the sunlight and retaining the moisture, two measures favorable to the continued growth and multiplica-

tion of the organisms.

One of the most effective of all therapeutic agents in this disease is, as every medical man knows, animoniated increary. The mistake most frequently made, however, is in the use of too strong a preparation of this drug. The official ointment funguentum

hydrargyri ammoniati, U. S. P.) consists of ten parts of white precipitate in ninety parts of benzoinated lard. The most satisfactory application is an

oily mixture, of one tenth this strength.

I commenced the use of a milder preparation by the advice of Norman Walker, of Edinburgh, who employs a one per cent. mercury petrolatum combination, but, probably owing to the greater value of olive oil as a skin penetrant, as well as its soothing effect on the inflamed epidermis, I have since found the following much superior:

each day.

The mixture is nonirritating, extremely efficient, and not unpleasant to use. If necessary, compresses soaked with the solution can be fixed, by means of bandages or adhesive plaster, directly over the affected areas. In addition to the curative action, the prophylactic effect is most excellent, further progress of the infection being immediately checked. Its value can be best appreciated in a severe case involving the bearded region of an adult male. A continuous application extending over a period of twenty-four hours will loosen all crusts and scales, the face is then carefully shaved, not too closely, and the oily dressing renewed. In this way a case which ordinarily requires from a fortnight to a month of treatment by the old methods can often be completely healed in a week.

It is difficult to explain why the mild preparation is so much more efficient than those containing considerable quantities of ammoniated mercury. I believe it is due to the fact that the stronger ones give rise to more or less irritation, with consequent exudation of serum. This combines with the mercury, forming the insoluble albuminate which not only possesses slight, if any, antiseptic power, but also serves to block the mouths of the infected channels and hinder the penetration of the active mercurial.

The general health must, of course, receive attention. Tonics, such as strychnine, arsenic, and iron, alone or together, are usully needed, with plentiful amounts of simple, nourishing food and daily exercise in the open air.

276 RIDGE BUILDING.

Accidental Infection with Glanders .-- An unusual accident occurred recently in the public institute for the examination of food at Czernowitz. Dr. Luksch, the chief bacteriologist, while making some investigations on the Bacillus mallei put a large quantity of the bacilli, obtained from an animal from the slaughter house, into a centrifuge. The tube containing the glanders bacillus burst and the contents were scattered over the laboratory. The fragments of glass were picked up by some of the persons working in the room, and, as it was believed that the bacilli were dead or inert, no great precautions were taken to prevent infection. In the course of a few days all those who were in the room at the time of the accident, developed symptoms of glanders, especially of the tracheal and pulmonary type, and two of the victims died within forty-eight hours of the onset of the disease. Dr. Luksch also fell ill .- Journal of the American Medical Association.

Our Benders' Discussions.

A SERIES OF PRIZE ESSAYS.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXVI.—How do you treat acute articular rheumatism?

(Closed July 15, 1908.)

LXXVII.—How do you treat varicose ulcer? (Answers due not later than August 15, 1908.)

LXXVIII.—How do you treat acute coryza? (Answers due not later than September 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred woords. words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the Journal.

The prize of \$25 for the best essay submitted in answer to question LXXV has been awarded to Dr. P. A. Smithe, of Enid, Oklahoma, whose article appeared on page 166.

PRIZE QUESTION LXXV.

THE TREATMENT OF CHOLERA INFANTUM. (Continued from page 170.)

Dr. Joseph Baum, of New York, observes:

It is exceedingly important in the treatment of this condition to have the intelligent cooperation of the mother; it is therefore advisable at the very beginning to explain to her in easily understandable language, what the disease is, and what your plan of treatment will be; inform her that more important than any drug, is the temporary starvation of the baby, with plenty of cool water, internally and externally; plenty of fresh air; and the regulation of the baby's diet and method of feeding. She must promise to follow your orders implicitly; she must be ready to temporarily neglect her other household cares: and last, but not least, she must not follow the well intentioned, but fallacious advice of a neighbor, but always, if in doubt, wait until she can see or hear from you. Written directions to a perplexed and nervous mother are of great service.

It is of prime importance that all feeding, especially milk, should be stopped for at least twentyfour hours; substitute barley water or rice water or albumin water at two hour intervals; explain this seeming radical step to the mother by stating that the digestive organs need a rest, and that barley and white of egg contain plenty of nourishment dur-

ing this brief starvation period

Start at once with a calomel series (the sheet anchor in all diseases of children); give doses of at least one sixth to one quarter grain repeated every fifteen minutes, until at least ten or twelve doses are given, and you get the typical, green calomel stools. Castor oil, if it can be retained, is of splendid service, on account of its soothing effect and constipating after effect; but it generally increases the infant's gastric distress, and sufficient is seldom retained to properly purge the baby. Instruct the mother to save some of the napkins, especially those containing blood or mucus, for your

inspection; always remember that diarrhoa is a conservative process of great value in cholera infantum.

The baby should be out in the air as much as possible; if circumstances permit the child to be taken to the country or preferably the sea shore, for a long or a short stay, the prognosis is almost invariably good; the tonic, enriching sea air has a wonderful effect on these cases; where removal from the city is impossible, advise the mother to go on the daily sea trips of the charitable organizations, or remain all day at the river's edge, on the docks or recreation piers; if for some reason she can not leave her home then erect some temporary shack on the roof of the tenement and have the baby kept on the roof, night and day, bringing its nourishment, medicine, etc., from the apartment below. If the baby's temperature is over 102° F. order a tub bath with the water at 100° F. and gradually reduce to 85° F. by adding cold water or lumps of ice; if tub baths are impossible, give sponge baths of alcohol and water; this bath or sponge bath is to be repeated before the baby is put to sleep at night, and if necessary every three hours during the day, if the temperature remains at 102° F. or over. If the physician would take the trouble to show the mother how a sponge bath should be given, it would be heartily appreciated by her, and be decidedly beneficial to the child. The strict injunction as to fresh air at all hours is very necessary, for the fear "catching cold" is still very prevalent in this enlightened age; sponge baths can be given with impunity in the open air, and the air seems to have a quieting soporific effect on the little unfortunate, and a fretful, irritable baby in the house generally falls into a long restful sleep as soon as it is placed in the open air.

Always watch the stools closely, for they are the index as to when feeding can be recommenced; when the mucus or blood disappears; when no more undigested particles of food are present, then is the time to start in with milk; still adhering to barley water as a basis, feed the baby every two, better every three hours, with a mixture of seven ounces barley water and one ounce boiled (and cooled) milk. This is not the place to go into the milk question, but obtain the milk at one of the various charitable milk depots in the city (and if in the country from the same cow every day); boil every morning sufficient for the day's supply, and then put it on the ice to be used when required; in the same way every morning, enough barley water should be made for the entire day's use; but each bottle should be warmed and mixed at each feeding time.

Mothers who nurse their babies are generally exempt from cholera infantum in their nurslings; babies should not be weaned in summer, and the longer a child is breast fed the less likely is it to get diarrhœa; if a nursling does get cholera infantum the same rules as to starvation, the temporary use of barley water, and all other treatment, as herein written, should be followed.

If improvement in all symptoms—vomiting, diarrhoa, fever, insomnia, etc.—continues, add every day an ounce of milk and diminish an ounce of barley water; if vomiting or diarrhoa recur, omit one feeding; if it continues, stop all milk and go back to plain barley water for a few feedings until

conditions are improved, and then gradually add the milk again. Sometimes cow's milk will not be well borne, even after patient effort; some of the various artificial foods should be tried and given a fair trial, until finally one is found which agrees with the baby; very often liquid peptonoids will carry you over a couple of bad days, until the stomach again is able to retain milk.

Avoid if possible the use of whiskey or other heart stimulant; if necessary use good brandy in very weak dilution; absolutely avoid the usual intestinal mixtures of chalk, pepsin, and paregoric; if the bowels seem uncontrollable use intestinal irrigations of a saturated solution of boracic acid, using a small size rectal tube or a soft rubber catheter attached to the irrigation tube.

If some intestinal astringent must be used, it is better to use it alone without admixture with other drugs; infants stand bismuth (suspended in mucilage) in large doses very well; as an opiate when every feeding is immediately followed by a painful rectal discharge of the entire feeding, use the deodorized tincture of opium, in small doses, given in plain water after each feeding; and this opiate must be given carefully and stopped as soon as the desired effect is accomplished.

Fifteen years' experience with tenement house babies has taught me that the main cause of cholera infantum is the overfeeding and too frequent feeding of improper food by careless mothers; it is also certain that careless medical advice, consisting usually of prescriptions of all kinds of mixtures containing opium in some form, is the main cause of the high percentage of mortality; the druggist who has no conscience, but who has a ten cent panacea for every disease, is also a very serious menace in the poorer districts of the city.

To sum up, if a physician at the outset will clearly explain to the mother every detail of his plan of treatment, insisting on absolute compliance with all his instructions, and emphasizing the fact that babies often die from overfeeding; that starvation for a short time, with plenty of water internally and externally; that keeping the baby in the fresh air as much as possible day and night, with proper regulation of feeding; that all these are the essentials, and that without her intelligent assistance the baby cannot improve, he will surely strike the tenderest chord of her maternal instincts, and she will prove to be a willing and self sacrificing ally. Then with a preliminary intestinal clearing out with calomel or castor oil; with watching the stools for the first sign that regular feeding can be recommenced; with watchful care over the heart, and giving drugs only when indicated, most cases will soon return to normal health.

This treatment covers the usual type of "summer diarrhoea," the acute intestinal indigestion, the cholera infantum we usually see in the heated term.

There is a type of cholera infantum which is of a most serious import from the very outset; although pathological studies have not absolutely isolated the causative bacterial factor, the cases seem septic from the first; it is a fulminating type of the disease, with every symptom of the simple type greatly intensified, and accompanied by rapid emaciation, almost incessant emesis and purging.

and with symptoms of cerebral complications, and generally ends in a stuporous, comatose condition and death. The most active treatment is indicated; baths, gastric lavage, intestinal irrigation, opiates, and cardiac stimulants, and of course removal to the sea shore if possible; but the prognosis is usually bad, and in spite of the most heroic treatment the child dies as if overcome by sepsis.

Dr. W. F. Clary, Jr., of Memphis, Tenn., states:

This disease is most common in the summer season, affecting chiefly infants in their first year of

life and especially the bottle fed.

Little is accomplished by treatment of an infant who is already overpowered by toxic materials, producing a train of symptoms known as cholera infantum. The child that a few hours ago was fat, possibly puffy, but apparently big and strong, is now melting away before the ravages of this poisoning as snow before a summer's sun. Prostration is very profound, and unfortunately this disease is so frequently rapidly fatal that little opportunity is allowed for treatment.

However, much can be done in the prevention of this malady. The issue of paramount importance is prophylaxis. Promptly and skilfully treat all mild intestinal disorders, as these so frequently pre-

cede an attack of cholera infantum.

Hygienic and dietetic measures must be rigidly enforced. By so doing intestinal disorders are reduced to a minimum. However, when an attack is present, it is necessary to counteract the shock to the nervous and circulatory systems, and the surest remedy is a hypodermic injection of morphine, 1/100 gr.; and atropine, 1/600 gr., for a child about one year old, to be repeated every hour until restlessness, vomiting, and purging are greatly diminished.

The next indication in the treatment is frequent irrigations of the large bowel with normal salt solutions through long, soft rubber catheter, with pelvis elevated. It is well to use a half gallon of this solution at a time, allowing it to run in and out freely. If the temperature is high these injections should be cold.

Control the temperature by frequent tepid baths, gradually lowering the temperature of the water, continuing baths for twenty or thirty minutes at a time. Ice bag or cold cloths should be applied to

the head.

There has been a great loss of fluid from the vomiting and the serous diarrhoea. Refund this loss by hypodermoclysis, which is the most prompt and sure remedy for this deficiency. One half to one pint of a normal salt solution should be injected into the cellular tissue in the course of twelve hours, or even more, according to the case.

As soon as the morphine and atropine injections have quieted the stomach to a moderate degree, give calomel, 1/10 gr.; pulv. ipecac, 1/20; and pulv. cap-

sic., 1/20 gr., every hour.

Beyond this nothing should be taken on the stomach, except water and crushed ice with brandy or champagne. When stimulants cannot be retained on the stomach and are necessary, hypodermic injections of brandy, ether, or camphor must be resorted to. Hot mustard baths, a mustard poultice

to abdomen, and hot water bottles should be placed about the patient. If the patient has reached a relaxed stage and is becoming drowsy, the stimulation must be used freely. It is now too late for the use of morphine. When the sphincter relaxes and the child sinks into a coma, your treatment is all in vain. If your patient has escaped this condition and soon shows signs of improvement, then the question of nourishment looms up before you. Every article of diet is fraught with more or less danger to the infant. You are greatly concerned as to what is best to use. Of all the various articles the ones which have yielded the best results are egg albumen; rice, barley, or oatmeal waters, or water in which toasted bread has been soaked. It is only by extreme care now that future trouble is to be avoided. If possible remove the child from the city to the country or to the sea shore for the remainder of the summer. Keep a watchful eye on the child, and never relent until every vestige of intestinal disorder has disappeared.

There is great danger in returning to a milk diet, and it should be deferred as long as possible. During convalescence it is well to keep the bowels regulated with aromatic syrup of rhubarb and castor oil, equal parts. Put forth every effort to prevent a

recurrence, but never over treat the case.

Dr. Samuel A. Loewenberg, of Philadelphia, says:

Cholera infantum as such is at present a comparatively rare disease, thanks to the better hygiene and education among the poor. Very often a simple case of diarrhœa in a child during the summer months is termed "summer complaint," the common name for this disease.

Cholera infantum is a very grave and rapidly terminating disease, second only to its sister, Asiatic The duration is from eight to twelve hours, terminating either in improvement or death.

The very severity of this affection calls therefore for immediate and heroic action. In fact, it should

be treated as an emergency case.

The treatment of this affection is divided into three classes: I, Prophylaxis; 2, treatment of the attack proper; and, 3, treatment of convalescence.

1. Prophylaxis.—Cholera infantum occurs, 1, al-

ways during the hot summer months; 2, usually in bottle fed children; and, 3, most often among those living in congested districts. The combination of the three is the rule, since they tend to lower the babies' vitality. We therefore must direct our attention to improving that vitality, by correcting as far as possible any condition which will most likely predispose the patient to this disease.

If the parents are able the child, usually weakly, should be sent to the country or sea shore. unfortunately the parents are usually poor, and cannot afford to go anywhere. We must therefore ob-

tan fresh air in the best possible way.

I have the child kept out doors as much as possible, at the same time avoiding the hot sun rays. The sleeping room should not contain any unnecessary hangings, and the windows are to be kept open, avoiding strong draughts.

I also instruct the mother to get three or four half hoops, and fasten them to the baby's crib, viz., one at the foot and one at the head of the crib, the remaining one or two to be placed at an equal distance from one another. This forms a perfect framework, upon which a very light cheese cloth is stretched, forming a tent, with sufficient space for rapid interchange of air. The object of this tent is to keep out flies, mosquitoes, bedbugs, and other insects which irritate the child.

The bedding is to be changed twice daily, or oftener if required; rigid cleanliness about the child and clothing is to be observed most religiously. The child should receive one and in very warm days two

lukewarm baths daily.

If the child is artificially fed, too great stress cannot be laid upon the most scrupulous cleanliness of the bottle and nipples. I usually have preference to a percentage milk, suitable for the individual case, the fat, proteids, and alkalinity being changed according to the child's condition, viz., bowels, thriving, and restfulness. In cases where the parents are not of sufficient intelligence to prepare the milk, I either have recourse to one of the malted foods or prepared milk. Diarrhæa, no matter how slight, requires immediate attention, for very often that is the starting point of this grave and serious disease. Constipation, like diarrhæa, requires attention, because both are expressions of a disturbed digestion.

2. Treatment of the attack proper.—Cholera infantum is ushered in as a rule suddenly, with marked prostration, which is progressive, with high temperature, and incessant vomiting, and an uncontrollable serous diarrhea. The treatment should therefore be to (a) assist Nature in relieving the irritated mucosa of the gastrointestinal tract; (b) supportive; (c) reduction of temperature; and (d)

feeding.

The vomiting and diarrhoa are Nature's method of assisting to aid the angry mucosa. We must therefore assist her in elimination. If the vomiting is incessant, and the child is rapidly losing strength, I introduce a small, soft, baby stomach tube, and wash out that organ with one or two pints of a warm, normal saline solution. After that I introduce six to eight ounces of a one half per cent. boric acid solution. Usually that stops the vomiting; should it, however, continue, two or three hours after the first washing, I again wash out that organ, with a normal saline solution; then I introduce a six to eight ounces of a one half per cent. tannic acid solution. An hour later the patient is to receive 1/10 gr. of calomel, 15 gr. of soda, every half hour, until two grains of calomel are taken. I also give one or two drops of I in I,000 solution of adrenalin chloride in a teaspoonful of water every hour until the pulse is of better tension and the vomiting controlled. (I have had good results in those really exhausted children with the adrenalin

a. Bowels.—I give personally a high rectal enema (colonic irrigation) with a warm normal saline solution, one quart. This is followed after ten minutes by a cold, normal saline, as a low enema, that is given to control the temperature. Three hours after the high enema, if symptoms still persist, I give another high enema, using one pint of a normal saline solution at 85° F., and follow immediately with another pint of one half to one per cent, of argyrol solution in water. In grave cases, where the vomiting and diarrhoea are uncontrollable, and

the child is wasting rapidly, I give a hypodermic injection of 1/100 gr. of morphine sulphate, with 1/800 gr. of atropine sulphate; the same is repeated within three or four hours if occasion demands it. If, in addition, the kidneys are inactive, six to eight ounces of a normal saline solution is given subcu-

taneously, usually in the buttocks.

b. Supportive.—Whiskey seems to have the best stimulating effect in these cases; as much as a drachm can be given diluted to a child of one year at a dose; if the stomach does not tolerate it then it may be given hypodermically. In extreme cases I/100 gr. of strychnine sulphate should be given hypodermically to a child, one year old, every three or four hours. If the heart beats very rapidly and pulse is weak, I/800 gr. of atropine is added. The exact dose depends largely upon the child's condition.

c. Temperature.—The temperature is controlled by the tepid and gradually cooled bath, which may be given every three hours if required. The colonic irrigations and low cold water enema also help in the reduction of the fever. If the temperature still remains high I have a cold compress applied to the abdomen, that to be changed as soon as it gets hot, allowing, though, an intermission of two hours. That is, the compresses are to be applied steadily for two hours, then stopped for two hours, then recommenced if necessary. The ice cap to the head, and if the feet are cold a hot water bottle should be applied to them. Should the temperature fall suddenly below normal and the heart be weak, high stimulation should at once be given and the body surrounded with hot water bottles.

d. Feeding.—All food should be withdrawn for the first eight hours, or until the violence of the attack has somewhat subsided. The thirst is usually great; while food is not allowed, I do give about one half ounce of sulphuric acid lemonade every half hour. After the acute symptoms have somewhat abated, I give first one drachm of albumen water every ten or fifteen minutes, that is, being gradually increased. Then I allow a little barley or rice water. The next food may be fluid peptonoids, 30 drops in water every two hours. As the patient progresses, we gradually increase his food to

whey, peptonized milk, etc.

3. Convalescence.—This stage must be as carefully treated in its way as the preceding stage, because recurrence is not uncommon. The patient should still get fresh air, "salt water" air if possible. Food should be gradually increased, all cleanliness as rigidly observed as before, and the movements of the bowels controlled, which at this time are not altogether well.

Summary. Prophylaxis: Clearliness, appropriate

ood, and fresh air.

Treatment of attack.—Clean out the stomach and bowel, support the patient, overcome shock, reduce temperature, etc., supply body juices. Meet any indication necessary, do it quickly, intelligently, and rationally.

During convalescence, guide the patient to his recovery, remembering the gravity of the previous disease.

If this summary is kept in mind, no one can go astray.

(To be concluded.)

Correspondence.

LETTER FROM LONDON

4 Sleeping Stekness Commission.—Sir David Bruce and Malta Fever.—Women Barred from the Royal College of Surgeons by Vote, but It May Be Oversuled by the Council.—The Sheffield Meeting of the British Medical

LONDON, July 14, 1908.

A new commission will shortly proceed to East Africa to investigate sleeping sickness. The first commission went out in 1902 and did a considerable amount of valuable work until 1905, when it was temporarily suspended owing to the death of one of the members of the expedition, Lieutenant Tulloch, who contracted sleeping sickness in Uganda. The new expedition, which is organized by the Royal Society, will be in charge of Sir David Bruce, and he will be accompanied by Captain Hamerton and Captain Bakeman, R. A. M. C. They will leave England on September 25th and travel by way of Mombasa to Lake Victoria, where the Uganda Proectorate is preparing a laboratory for their use. The commission will investigate the natural history of Glossina palpalis and also Dr. Koch's theory that crocodiles provide food for the fly.

Dr. Bruce has just received a knighthood for his researches in connection with Malta fever, and he has also been awarded the Stewart Prize by the Science Committee of the British Medical Association for this work. The story of the discovery of the mode of infection in this disease, by goat's milk, forms an extremely interesting example of the value of experiments on animals to medicine. The great value of the discovery is shown by the fact that, whereas formerly Malta was considered one of the most unwholesome spots by Englishmen, and was dreaded by the officers and men of the army and navy, it is now one of the healthiest of garrisons. Thus, in 1905, before the discovery that goat's milk was the source of infection, there were 643 cases of Malta fever on the island. In 1907, when the cause had been found and preventive measures taken, the number of cases dropped to seven, truly a remarkable result.

The result of the poll of the members of the Royal College of Surgeons, as regards the admission of women to the membership and fellowship, has now been declared. Out of a possible 1,373. 1,053 fellows, and out of about 13.800 members available, 8,543 recorded their votes. The result was surprising. It shows a majority of 415 votes against the admission of women to the membership and a majority of 1,182 against their admission to the fellowship. It was expected that the voting would be in favor of the admission of women as members, but not as fellows. As a matter of fact the fellows of the college by themselves were in favor of the innovation, but their votes were outnumbered by those of the members. Of course, the council are not bound to act according to the voting, and it is very probable that women will be admitted in spite of the adverse vote, but the council has not yet come to a final decision. The members of the college have a grievance, as they are not allowed to have a seat on the council. But, as the

Roya! College of Surgeons is a purely scientific body and does not deal with medicopolitical matters, it can scarcely represent the interests of the general practitioners, though most of the members belong to that class, and it is perhaps an advantage that the council should be limited to those fellows who by strenuous and distinguished devotion to surgery have entitled themselves to that distinction. Apart from that, ample provision for dealing with matters affecting general practitioners is made by other tribunals, and there is no reason for the council to occupy themselves with such matters.

Arrangements are now complete for the annual meeting of the British Medical Association, to be held in Sheffield early next week. The president elect is Mr. Simeon Snell, F. R. C. S., ophthalmic surgeon to the Royal Infirmary, Sheffield, who will succeed Dr. Henry Davy, of the Royal Devon and Exeter Hospital. An interesting programme has been arranged by the local secretaries, and members of the association will have the opportunity of visiting several of the historic mansions situated in the country near Sheffield. The list of the papers to be read has been published, and several of them promise to be extremely interesting.

Therapeutical Hotes.

For Night Sweats in Phthisis.-For the suppression of excessive perspiration, the following prescriptions are suggested by Courtois-Suffit and Tremolières, previously cited:

| | I. |
|--------------|---|
| \mathbf{R} | Pulverized white agaric,gr. vi |
| | Calcium phosphate,gr. ix |
| | Pulverized opium,gr. 13 |
| M. | ft. cachet i. Sig.: One cachet once or twice daily. |
| | II |
| \mathbf{R} | Ergotine,gr. 13 |
| | Lactic acid |
| | Boiling distilled water,q. s. ad xv |
| M. | |
| | III |
| \mathbf{R} | Sage leaves, |
| | Distilled water, |
| M | et sig. Make an infusion and take at one time after |

it has cooled. IV. fore the sweating comes on.

Sig.: One pill at night. (Four pills is the maximum

If the state of the digestion militates against the use of pills the following may be given hypoder-

Sig.: Ten to twenty drops to be injected hypodermically.

To Control Hæmorrhage in Phthisis.--In hæmoptysis absolute rest and quiet must be ordered, and the patient kept exposed to pure air not overheated. The cause should be searched for and overcome, if possible (exposure to the sun, digestive disturbances, etc.). Hot foot baths and sinapisms should be used. Dry cupping, turpentine compresses, or chloroform may be used as indicated, but do not blister or apply the cautery. If the bleeding is very copious, tie a bandage tightly around the arms and legs close to the trunk,

The internal treatment consists of the administration of ergot, either as ergotine in fiteen to thirty grain doses administered hypodermically during the day, or as freshly pulverized ergot of rye combined with quinine, as in the following prescription:

| B I | reshly | pulveria | zed er | got, | | | | | gr. | iii |
|-------|-----------|----------|---------|------|-----|--------|-------|------|--------|-----|
| | Quinine | sulphate | e, | | | | | | gr. | iss |
| | t ft. cac | | | | | | | | | |
| Sir . | One | anchet . | 0370437 | half | hou | 197 17 | us+i1 | 0.42 | offect | - 1 |

Sig.: One cachet every half hour until an effect is produced.

In grave hæmorrhage injections of gelatin serum should be employed, the gelatin used having been previously sterilized in an autoclave to avoid the danger of tetanic infection. The following formula for gelatin serum is proposed:

| \mathbf{R} | Gelatin | (carefully | st | e | ril | liz | ze | d | а | t. | 24 | 18 | 0 |] | F. |) | , | | | | | 3s | S |
|--------------|-----------|------------|----|---|-----|-----|----|---|---|----|----|----|---|---|----|---|---|---|---|--|----|----|---|
| | Distilled | water, | | | | | | | | | | | | | | | | | ۰ | | | Oi | ì |
| | Sodium | chloride, | | | | | | | ٠ | | | | | | | | | ٠ | | | gı | | C |
| M. | | | | | | | | | | | | | | | | | | | | | | | |

Inject five to six drachms of the solution and repeat two or three times a day for two or three days in succession.

(The article from which we have quoted concludes with advice and prescriptions for the treatment of other conditions usually associated with pulmonary troubles, and such as are deemed of value and interest will be reproduced in later issues.)

Application in Chronic Pharyngitis.—The following is applied as a paint by Heindl (cited in Journal de médecine de Paris, May 23, 1908) in the treatment of chronic pharyngitis:

| | Trichloracetic | | | |
|-----|---|-----|------|--------------|
| | Ferric iodide, Potassium iod | id. | | gr. ii ; |
| | Glycerin, | | | |
| 7.4 | 01,111111111111111111111111111111111111 | | | |

The Expulsion of Tapeworms.—Schilling (Therapeutische Monatshefte, April, 1908) advises the administration of a large dose of oleoresin of aspidium combined with pulverized jalap to be given in two portions within a period of thirty minutes. The following is the prescription:

The evening before the administration of the anthelmintic the patient should be fed with soap, and a quarter of an hour before the medicine is taken he should be given some black coffee with sugar, or make a light breakfast of bread and coffee. The worm is expelled as a rule in three or four hours. During this time the patient must fast. If the worm does not come away quickly a rectal injection of warm water (one or two pints) should be given.

Liquid Soap for Surgeons' Use.—To replace the ordinary white soap used for washing the hands of surgeons, M. Richaud (Précis de thérapie et de pharmacologie; Répertoire de pharmacie, June 10, trost advises the use of a liquid soap made accord-

ing to the following formula, which, he says, produces a saponaceous fluid which is very frothy and penetrable:

| P_k | White | soap | | | | | | | | | | | | | | 1000 | part-; |
|-------|---------|--------|------|----|------|-------|---|------|---|----|---|------|--|--|---|-------|--------|
| | Soft so | oap, . | | ٠, | | ٠ | ٠ | | | ٠. | ٠ | | | | | 1000 | parts; |
| | Poppy | oil, | | | | | | | | | | | | | , | . 500 | parts; |
| | Water, | | | | | | | | ٠ | | | | | | | 3000 | parts. |

The white soap is scraped, mixed with the other ingredients, and the whole heated to form a paste, to which is added:

| Glycerin,50 | parts; |
|-----------------------------|--------|
| Betanaphthol,50 | parts; |
| Alcohol (90 per cent.),500 | parts; |
| Oil of lemon,50 | parts; |
| Water,enough to make 15,000 | parts. |

Enema for Relieving the Bowels in Intestinal Colic.—At the House of Relief of the New York Hospital the following enema is given for the relief of intestinal colic:

| P_{i} | Oil of turpentine, | |
|---------|------------------------|---|
| | Oil of cotton seed, | |
| | Water, enough to make. | |
| | water, chough to make, | ٠ |

To the mixture formed by the first three ingredients add one pint of hot water, to be followed by sufficient additional cold water to make the whole measure two pints. The best results are obtained by using a bulb syringe and soft rubber rectal tube, inserting the tube high up.

Sodium Metavanadate for Anorexia.—According to an extract from La Pratique thérapeutique in La Clinique, sodium metavanadate is useful as an appetizer in the anorexia that accompanies pulmonary tuberculosis. It is prescribed thus:

| | | metavanadate, | | |
|-----|-----------|---------------|------|--|
| 7.4 | Distilled | water, | | |

Sig.: One tablespoonful to be taken half an hour before each meal.

It is not advisable to prolong the use of the sodium metavanadate solution beyond five or six days.

To Overcome Dysphagia in Pulmonary Tuberculosis.—The difficulty in swallowing experienced by phthisical patients is overcome to some extent by the application as a paint to the larynx by means of cotton wound around the point of a probang of the following:

| \mathbf{R} | Cocaine hydrochloride,gr. ivs | s; |
|--------------|---------------------------------------|-----|
| | Morphine hydrochloride,gr. 3 | |
| | Distilled water, 吸 lxx Glycerin, 透 | |
| 3./ | Glycerin, | 55. |

Insufflations of powders containing cocaine, morphine, orthoform, anæsthesine or similar substances through a suitable tube into the larynx are also recommended, the following being typical prescriptions:

| | I. |
|----|-----------------------------------|
| 14 | Cocaine hydrochloride,gr. 1/7; |
| | Morphine hydrochloride,gr. 1/12; |
| | Pulverized sugar of milk,gr. iss. |
| M. | Ft. pulv. No. 1. |
| | II. |
| 11 | Orthoform, |
| | Pulverized sugar of milk, |

M. Ft. pulv. No. 1.

NEW YORK, SATURDAY, AUGUST 1, 1908.

STATE EXAMINATIONS.

In our last issue, in an article entitled Obstacles in the Way of the Practitioner (page 172), we made certain remarks concerning the futility of some State examinations as tests of a candidate's fitness to enter upon the practice of medicine. Since that article was prepared we have received the July number of the Albany Medical Annals, in which there is published a brief but important paper by Dr. Willis G. Tucker, professor of chemistry in the Albany Medical College, "prepared by request for the Fourth Annual Conference of the Council on Medical Education of the American Medical Association, held in Chicago, April 13, 1908." Dr. Tucker is a veteran teacher of chemistry in its relations to medicine and an educator of ripe experience. We have before had occasion to cite his views, which are always expressive of sound judgment and stated with all possible fairness and courtesy. We are now particularly gratified to meet with this latest communication of his, because it amply justifies what we said last week. Dr. Tucker quotes the following chemistry paper, "set at a recent examination in a great State":

- I. What is valency?
- 2. What characteristic reaction would ozone or hydrogen dioxide have on potassium iodide?
- 3. Complete this formula (sic): Na,SO₄ + 2C + CaCO₈ =.
- 4. What is formed by treating hydrochloric acid with manganese dioxide?
 - 5 Complete this formula (sic): K,O+2C=

Dr. Tucker comments as follows:

I have been engaged in teaching chemistry in a medical school and elsewhere for over thirty years, and have no hesitation in saying that this paper is entirely inadequate and absolutely worthless as a test of a man's knowledge of chemistry as related to medicine and in determining his competency to practise medicine. Only two of the questions, the second and fourth, have any bearing upon medicine, and, while the fourth is simple enough, it is comparatively unimportant for the reason that chlorine is not ordinarily generated on a large scale in the manner specified. The first question might be retained if the number of topics had been greater, but to give so much weight to a matter like valency in a medical examination is entirely unjustifiable. The third question has to do with the chemical changes taking place in the manufacture of soda ash by the old process, and, while proper enough in its place, is of no more interest or importance to the student or practitioner of medicine than the canals of Mars. The last question assumes the existence of an oxide of potassium that I never heard of and which has, I believe, no existence. The examiner had in mind the reaction taking place in the manufacture of metallic potassium, which I conceive to be a procedure as far removed from everything medical as the manufacture of furniture polish or shoe blacking. This paper may be objected to on the lawyer's grounds-that three fifths of the questions are incompetent, immaterial, and irrelevant. The possession of such information proves nothing as to medical competency, and the lack of it should be allowed to debar no man from securing his license. I doubt whether one member in ten on our State boards, save perhaps the examiners in chemistry, could get forty per cent. on such a paper as this.

We agree entirely with Dr. Tucker in his strictures, and we are also of his opinion when he says that no medical school could fit a man to pass such examinations, unless, indeed, it wasted time that ought to be devoted to really medical instruction. Dr. Tucker thinks that many State examining boards are improperly constituted, that unfit persons are selected as their members, and he would have them made up of those who have had experience in medical teaching. We would add, in medical practice also. Evidently the average State examination is no trustworthy criterion of a candidate's title to the license to practise.

THE ATTEMPTED SUPPRESSION OF DIN.

New York is a noisy town, far noisier than is at all necessary or easily supportable. For many of its noises there is no pretense even of apparent necessity; on the contrary, those who cause these noises do so in a spirit of bravado and with the set purpose of tormenting their fellows. The man who has a load or an article of merchandise to deliver on the sidewalk takes pains to drop it as noisily as he can, sleep is murdered by the nocturnal trucking of steel beams without any padding, the bodies of two-wheeled carts are made to proclaim the

horse movement loudly, chauffeurs "honk" almost incessantly their insolent "get out of my way," the hawkers bark their raucous cries most maddeningly, the scissors grinders bray their mockeries of bugle calls, and at midnight Jennie Leatherlungs joins her din to the atrocious staccato "virtuosity" of the professional piano thumper and the calls of coachmen waiting in line in a block in which an evening entertainment happens to be going on.

Of course we must submit to necessary noises, of which there will always be a plenty, but we hope that the Police Department's movement for the suppression of the unnecessary ones will suffer no abatement. Only the "old clo" men seem to oppose it seriously, and their trade is hardly important enough to entitle it to exemption. It is on the sick, of course, that the multifarious street noises work their worst, and one would think that the Health Department might be justified in taking a hand in their suppression. As it is, no one city department seems to have made the effort purely of its own volition; several years ago Dr. John H. Girdner tried to rouse a popular demand for the extinction of unnecessary and indefensible clang, and more recently Mrs. Rice has labored valiantly in the same direction. Perhaps their efforts are now bearing fruit in the execution of General Bingham's edict. The New York Herald, which may fairly be said to have carried on a crusade of its own against street din, is also entitled to much credit.

Sweet church bells have been almost silenced in this community, in order that the Sunday morning naps of the lazy might not be curtailed, and the really useful bell fire alarm system was long ago discontinued, though perhaps not for fear of disturbing anybody. Why, then, should not the cry of the sick and the overworked be heeded when it comes to a question of din that is hideous and perfectly avoidable? It is the duty of all good citizens, and particularly of the medical profession, to do everything in their power to strengthen the hands of those who have at last made an authoritative attempt to save us from "the blows of sound."

CLEANLINESS AN ELEMENT OF PURITY IN FOODS.

The active crusade against filthy lunch rooms and restaurants which was recently inaugurated by the efficient health officer of the District of Columbia suggests a direction for the activity of city health officials generally which will surely be productive of good. In every large city there are hundreds of small restaurants and lunch rooms which are conducted in such an unsanitary manner as to make them breeding places of disease.

It may be objected that such conditions necessarily accompany any effort to reduce the cost of food to the low level demanded by the patrons of restaurants of this class, but such assertions have been abundantly disproved by the experiments made by the leaders in what is generally termed "social economics." The success of certain establishments has demonstrated that cleanliness and cheapness may go hand in hand, and quite recently a young woman has established a kitchen where meals are supplied at an exceedingly low cost, a full meal being furnished for about eight cents.

POLIOMYELITIS.

The search for the ætiological factor in anterior poliomyelitis has thus far been fruitless. Bacterial cultures have, for the most part, been negative, and the statements of those who have professed to have obtained positive results have been, thus far, unsupported. The recent New York epidemic of this disease placed a large amount of material under survey, the results of some of which are before us in an excellent study by Dr. Martha Wollstein, entitled A Biological Study of the Cerebrospinal Fluid in Anterior Poliomyelitis (Journal of Experimental Medicine, July).

The author's idea was that, if the disease was due to an undiscovered microorganism which could not be detected microscopically, it might still be possible to find evidence of its presence by demonstrating its specific antigen (in the sense of the Bordet, Wassermann, and Bruck reactions). Since the disease is localized in the spinal cord and brain, she considered it not improbable that the antigen might find its way into the cerebrospinal fluid. Early cases then might show the antigen in the cerebrospinal fluid and late cases might, assuming an infectious antigen producing organism as a cause, show the presence of antibodies discoverable in the blood serum or in the spinal fluid itself.

Cerebrospinal fluid was obtained by lumbar puncture in some twenty cases, at times varying from the second day to the eighth week of the disease. In every instance the fluid was clear and colorless, save when occasionally mixed with blood. Continual experiments showed it to be sterile in fifteen cases; in five, growths occurred; one was that of a white staphylococcus, a second was that of a Gram positive bacillus, and three were those of a large Gram positive coccus apparently similar to the organism described by Giersvold as having been found in twelve cases of the Norwegian epidemic and by Harbitz and Scheel in three.

The study of the serum reactions, in one case that came to autopsy, showed that no two interacting substances, presumably antigen and antibody, capable of uniting and anchoring complements, were demonstrable in the blood serum, cerebrospinal fluids, and organ extracts studied. Therefore, the diagnosis of poliomyelitis by means of a serum reaction was apparently not possible, and no light could be thrown on the ætiology of the disease by this reaction.

MALARIA IN CYPRUS.

A Cyprian weekly newspaper entitled Σάλπις presents in its issue for June 12th a leading editorial on malaria (ἐλωνωσία) in Cyprus, taking as its text Dr. Achilles Rose's article on Malaria in Greece, published in the New York Medical Journal for April 11th. It depicts the ravages of malarial disease in Cyprus, and calls on the Greek government to rouse itself to energetic measures for draining the marshes and exterminating mosquitoes, even going so far as to suggest that the British government, the Liverpool School of Tropical Medicine, and Sir Ronald Ross be called upon to aid in the undertaking.

PLASTER OF PARIS IN THE TREATMENT OF SMALLPOX.

Few of us have had a large experience in the treatment of smallpox, and so, unconsciously taking it for granted that the same deficiency of actual observation holds good in the case of others, we are apt to put too much confidence in published accounts emanating from those whose opportunities have been limited. But surely we may ascribe importance to the views of a practitioner who speaks on the strength of an experience of more than 450 cases occurring partly in hospital and partly in private practice. Such a man, as we learn from the Semaine médicale for July 15th, is Dr. I. Zdanovitch, a Russian physician. It is true that he speaks only of the palliative, or local, treatment, but that is very important in smallpox.

Zdanovitch finds that dry plaster of Paris is by all odds the best application for diminishing the suppuration and mitigating the subsequent pitting, as well as for allaying the intense itching and overcoming the loathsome odor of the disease. Its good effects are, of course, most noticeable in severe cases of confluent smallpox, those that are prone to terminate in deep cicatrices and actual deformity of the face. The use of plaster has the advantages, by no means inconsiderable, of being simple and of coming within the means even of the poorest families.

The patient is put to bed entirely nude, as is done in cases of extensive burns, and the skin is covered with a thick layer of drv plaster of Paris, which, of course, must be freshly ground. If at any time pus is seen to have oozed through the plaster, the powder is renewed at the oozing points. The patient is covered with light bedclothes, nothing but a sheet if the weather is warm. Under the influence of this application the repulsive odor soon disappears, because the plaster, by virtue of its affinity for water, absorbs the pus and thus hinders its decomposition. and this is particularly needful in situations where there are deep folds of the skin. The alleviation of itching is said to be very decided. Under this treatment the secondary fever, or fever of suppuration, often does not occur at all, for the pus is so thoroughly imbibed by the plaster that it has but little chance of being absorbed into the system. The dressing does not prove irritating, though there may be a slight sensation of smarting in case there is an exposed granulating surface.

THE "ÆSTHETIC" TREATMENT OF FRACTURE OF THE CLAVICLE.

All methods of treating fracture of the collar bone are conducted, so far as we know, with prominent attention to the object of obviating unsightliness of the injured part when the broken bone has undergone repair, but in a recent Paris thesis, as we learn from the *Presse médicale* for June 13th, in an article signed "J. D.," M. Hérard applies the term "æsthetic" par excellence to a procedure recommended by M. Couteaud about a year ago, at a meeting of the Paris Surgical Society held on June 12, 1007.

The patient is to lie at the extreme edge of a hard bed, with the arm of the injured side hanging down clear of the bed, not resting on anything. The weight of the arm is intended to drag upon the outer fragment of the broken clavicle and thus maintain coaptation. After two or three days, when spasmodic action of the muscles has been overcome, the irksomeness of the position may be mitigated by placing a cushion under the forearm flexed upon the arm. This attitude is to be maintained until union of the fragments has taken place. Out of eleven cases treated on this plan, nine, it is reported, resulted in union with perfect position; in the two others the method seems not to have been adhered to rigidly.

It is said that the patient soon grows accustomed to the enforced quiescence, though it is admitted that the tingling in the arm is at first very hard to bear. Œdema, as we can quite well understand, may be prevented by bandaging the arm. It seems to us that this sort of treatment must be little short of torture. To lie motionless on the back for days together, as patients are sometimes instructed to do after laparotomy has been performed upon them, is more than most flesh and blood can endure, and we believe that the injunction to do so is rarely obeyed. When to this is added the maintenance of strict abstention from moving an arm, the patient's condition must be really pitiable. Perhaps there are some young women whose great desire to preserve a faultless outline may serve to enable them to submit to the treatment, but we doubt if any ordinary man would consent to keep it up for the requisite length of time, two or three weeks.

Dbituary.

HORACE YOUNG EVANS, M. A., M. D., of Philadelphia.

Dr. Evans died in Breakwater, Maine, near Rockland, on Thursday, July 2d. He was born in Ches-·ter County, Pa., on October 14, 1834. He received the degree of bachelor of arts from Princeton in 1855, and subsequently took the master's degree. He was graduated from the Medical Department of the University of Pennsylvania in the class of 1858. He then took postgraduate work in Edinburgh, London, and Paris. In 1860 he entered the United States army as surgeon to the Philadelphia City Troop, and remained in the army until the fall of Richmond.

Dr. Evans was president of the Philadelphia County Medical Society in 1882. He was a fellow of the College of Physicians of Philadelphia and was one of the censors of the college. He was also a member of the Philadelphia County Medical Society, the Medical Society of the State of Pennsylvania, and the American Medical Association.

WILLIAM ELMER, M. D., of Trenton, N. J.

Dr. Elmer, who was born in Bridgeton, N. J., in 1840, died at Atlantic City, N. J., on Sat-urday, July 18th. He came of a long line of physi-cians, being the third William Elmer in three successive generations of medical men. The physicians in this family run back two generations beyond the first Dr. William Elmer. In 1869 Dr. Elmer moved to Trenton, N. J., where he had resided since. He was a former president of the Medical Society of the State of New Jersey, and at the time of his death was the director of the Mercer Hospital in

Dr. Elmer's personality endeared him to his many friends in the medical profession in Trenton and other places. He was in his sixty-eighth year.

Rews Atems.

The Regents of the University of Utah announce that hereafter no student, teacher, or employee infected with tuberculosis will be admitted to the class rooms, or to the

Typhoid Fever Epidemic at Hastings, Pa.—Hastings is a town in Cambria County, of about 1,600 population. Twenty-one cases of typhoid fever were reported from there during the week ending July 16th.

The Rhode Island Medicolegal Society met in annual Section recently and elected the following officers for the

session recently and elected the following officers for the ensuing year: President, Dr. A. H. Longfellow; vice president, Dr. George H. Huddy, Jr.; secretary and treasurer, Dr. C. R. Dotem.

Personal.—Dr. F. Raymond, of the University of Paris, has received from Oxford University the degree of

doctor of science.

Dr. O. J. Hager, of Moorehead, Minn., is registered at the Philadelphia Polyclinic and College for Graduates in Medicine

The British Columbia Medical Association will hold its annual meeting at Vancouver on August 20th and 21st. Among those who will present papers at this meeting are Dr. Joseph Price, of Philadelphia, and Dr. Bingham, of Toronto. Dr. J. M. Pearson, of Vancouver, president of the society, will preside.

the society, will preside.

Contagious Diseases in Chicago.—During the week ending July 18, 1908, 240 cases of communicable diseases were reported to the Department of Health. Of these 58 were of measles, 55 of scarlet fever, 41 of diphtheria, 31 of whooping cough, 31 of tuberculosis, 17 of typhoid fever, 4 of chickenpox, 1 of smallpox, and 2 of diseases of minor inventures. importance

The New York Eye and Ear Infirmary.—Plans have been filed for the enlarging of this institution, which is situated in Thirteenth Street, near Second Avenue. A third story is to be added, which will be fitted up as an isolation ward, to afford enlarged space for the general hospital service of the infirmary. The improvements will cost about \$5,000.

cost about \$5,000.

Richmond, Va., Academy of Medicine and Surgery.—

A meeting of this academy was held on the evening of Tuesday, July 28th. The programme included a paper on Indications for Surgical Treatment of Diseases of the Brain, by Dr. J. Shelton Horsley, and a paper on the Results of Gastric Surgery, by Dr. J. W. Henson. The gental disease is a factor program of the Results of Gastric Surgery, by Dr. J. W. Henson. The gental disease is a factor program of the Results of Gastric Surgery. eral discussion of these papers was opened by Dr. Stewart McGuire

The Alvarenga Prize of the College of Physicians of Philadelphia was awarded to Dr. William T. Shoemaker, of Philadelphia, for the essay entitled Retinitis Pigmentosa, with an analysis of seventeen cases occurring Pigmentosa, with an analysis of seventeen cases occurring in deaf mutes; including laboratory examinations of the blood and urine in eleven cases. The laboratory examinations were made by Dr. John M. Swan, of Philadelphia. Charitable Bequests.—By the will of the late Rev. Hugh P. Smyth, St. Elizabeth's Hospital, Boston, receives

\$5,000.

By the will of A. J. Macky, the town of Boulder, Col., receives the sum of \$50,000 to maintain a hospital and home for indigent widows and orphans.

By the will of Mary Burt, the Pennsylvania Industrial Home for Blind Women of Philadelphia receives \$2,000

Change of Date of the Meeting of the American Hospital Association .- Announcement is made by the local Committee of Arrangements that, owing to the impossibility of securing adequate hotel accommodations in Toronto during the week of September 22d, or earlier, the date of the tenth annual meeting of the American Hospital Association has been changed. The conference will be held at the King Edward Hotel, Toronto, on September 20th and with and October 1st and 20th and Suggistal Association between the conference will be a conference with the con

The Chattahoochee Valley Medical and Surgical As-

The Chattahoochee Valley Medical and Surgical Association held its fourth annual meeting in Auburn, Ala., on July 15th, and elected the following officers for the ensuing year: Dr. J. H. McDuffie, of Columbus, Ga., president; Dr. J. G. Palmer, of Opelika, Ala., first vice president; Dr. J. Love, of Opelika, Ala., second vice president; Dr. W. J. Love, of Opelika, Ala., secretary; Dr. A. J. Coley, of Alexander City, Ala., treasurer. The meeting was a president; the rest interest. ing was largely attended, and was one of the most interest-ing and instructive ever held by the association.

Floyd County, Ga., Medical Society.—The regular monthly meeting of this society was held in Rome on Saturday, July 25th, at 10:30 a. m. The general subject for discussion was Obstetries. Dr. Robert H. Wicker read a paper on the Hygiene of Pregnancy. Dr. A. C. Shamblin read a paper on Abortion. Dr. James E. Ivey, Dr. W. J. Shaw, and Dr. Turner presented reports of interesting cases. The general discussion was onened by Dr. James C. The general discussion was opened by Dr. James C Watts.

The Franklin District, Mass., Medical Society held a meeting on Tuesday, July 14th, in Greenfield. The programme included a paper on Pneumonia by Dr. F. E. Johnson, of Erving, and the report of a case of carcinoma of the pancreas by Dr. J. A. Mather, of Colrain. The next meeting will be held on September 8th. Papers will be read by Dr. Charles L. Upton, of Shelburne Falls, Dr. John E. Urquhart, of Ashfield, and Dr. Francis E. Johnson, of Erving. The officers of the society are: President, Dr. J. W. Cram, of Colrain; vice president, Dr. C. L. Upton, of Shelburne Falls; secretary and treasurer, Dr. Clara M. Craescowich of Graesfield.

Greenough, of Greenfield.

A Crusade to Reduce the Infant Mortality of Chicago .- A systematic effort is being made in Chicago to reduce the death rate among babies in the tenement district. The city council has transferred \$10,000 from the contagious disease fund to a special fund to be devoted to the care of children during the hot weather, and seventyfive physicians have been engaged to carry on the work of educating mothers in how to feed and care for babies. A thorough sanitary inspection is being made of all milk depots and stores handling milk, and cards are being distributed in this district warning parents to take care that

no unclean milk is fed to the babies.

Assistant Surgeon Wanted for Freedmen's Hospital. -The United States Civil Service Commission announces that an examination will be held on September 2 and 3, 1908, to secure eligibles from which to make certification to fill a vacancy in the position of first assistant surgeon (male) at Freedmen's Hospital, at \$1,500 a year, and vacancies requiring similar qualifications as they may occur at the hospital. Freedmen's Hospital is an institution for the treatment of colored patients, and it is understood to be the practice of the department to appoint only colored persons to positions therein. Applicants must be citizens of the United States and twenty years old or over on the date of the examination. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for application Form 1312.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending July

| | - July | / IS | ui | y 25 |
|--------------------------|--------|---------|--------|--------|
| | | Deaths. | Cases. | Death- |

The Mortality of Chicago.—During the week ending July 18, 1908, there were reported to the Department of Health of the City of Chicago 526 deaths from all causes, as compared with 510 for the preceding week and 500 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.66. Of the total number of deaths 151 were of children under one year of age, and 36 deaths 151 were of children under one year of age, and 30 of children between one and five years. The principal causes of death were: Apoplexy, 8; Bright's disease, 33; bronchitis, 3; consumption, 66; cancer. 28; convulsions, 5; diphtheria, 2; heart diseases, 53; influenza, 1; intestinal diseases, acute, 96; measles, 2; nervous diseases, 13; pneumonia, 21; scarlet fever, 4; suicide. 10; sunstroke, 4; tetanus, 1; typhoid fever, 3; violence (other than suicide), whooping cough, 2; all other causes, 138.

The Health of Pittsburgh.—During the week ending the control of the first property of the control of the control

July 11, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 2 cases, o deaths; typhoid fever, 26 cases, I death; scarlet fever, 13 cases, 1 death; diphtheria, 5 cases, 1 death

measles, 55 cases, 3 deaths; whooping cough, 15 cases, 0 deaths; pulmonary tuberculosis, 21 cases, 5 deaths. The total deaths for the week numbered 147, in an estimated population of 565,000, corresponding to an annual death rate of 13,70 in 1,000 of population. During the week ending July 18th the following cases of transmissible diseases ing July 16th the following cases of transmissions were reported: Chickenpox, I case, 0 deaths; typhoid fever, 27 cases, 5 deaths; scarlet fever, 7 cases, 1 death; diphtheria, 6 cases, 0 deaths; measles, 57 cases, 4 deaths; whooping cough, 10 cases, 1 death; pulmonary tuberculosis, 29 cases, 13 deaths. The total deaths for the week numbered 196, corresponding to an annual death rate of 18.03 in 1,000 of population.

Vital Statistics of New York .- During the week ending July 18, 1908, there were reported to the Department of Health of the City of New York 1,567 deaths from all causes, as compared with 1,516 for the preceding week and 1,555 for the corresponding period in 1907. There were 755 deaths in Manhattan, 138 in the Bronx, 547 in Brooklyn, 97 in Queens, and 36 in Richmond. The annual death rate in 1,000 of population was 18,48 for the whole city, and the state of the five because it was as follows. Machattan for each of the five boroughs it was as follows: Manhattan, 17.18; the Bronx, 21.08; Brooklyn, 19.12; Queens, 20.41, and Richmond, 24.49. The total number of deaths of children under five years of age was 703, of which 426 were due to diarrhœal diseases. There were 173 deaths from pulmonary tuberculosis during the week, as against 152 for the corresponding period in 1907. The deaths by violence numbered 121, of which 27 were from sunstroke, 3 from homicide, 16 from suicide, and 75 from accidents. Four hundred and eighty-nine marriages, 2,263 births, and 116 still births were reported during the week

The Health of Philadelphia.—During the week ending July 18, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 24 cases, 6 deaths; scarlet fever, 25 cases, o deaths; chickenpox, 8 cases, o deaths; diphtheria, 32 cases, 4 deaths; cerebrospinal meningitis, 2 cases, o deaths; measles, 63 cases, 4 deaths; whooping cough, 35 cases, 10 deaths; pulmonary tuberculosis, 101 cases, 48 deaths; pneumonia, 24 cases, 24 deaths; erysipelas, 2 cases, 0 deaths; puerperal fever, I case, o deaths; trachoma, 5 cases, o deaths; cancer, 18 cases, 20 deaths; mumps, 2 cases, o deaths; tetanus, 2 cases, I death. The following deaths were reported from other transmissible diseases: Tuberculosis, other than cases, I death. The following deaths were reported from their transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 14; diarrhoea and enteritis, under two years of age, 115; dysentery, 1; cholera morbus, 2. The total deaths numbered 517 in an estimated population of 1,532,738, corresponding to an annual death rate of 17,50 in 1,000 of population. The total infant mortality was 237; under one vary of age, 187; between one and two was 227; under one year of age, 187; between one and two years of age, 40. There were 23 still births, 10 males and 13 females. There were 7 deaths from heat and sunstroke, 4 adults and 3 minors.

Clinical Director Wanted for the Government Hospital for the Insane.—The United States Civil Service Commission announces an examination on August 26, 1908 to secure eligibles from which to make certification to fill a vacancy in the position of clinical director in the Government Hospital for the Insane, Washington, D. C., at a salary of \$2.500 a year, with maintenance in the hospital, and vacancies requiring similar qualifications as they may occur in any branch of the service. To become eligible, the applicant must be a graduate of a regularly incorporated medical college, must have had at least ten years experience in institutions for the care and treatment of the insane, during which period he must have received training with special reference to work along clinical lines, research work, in pathology, and in psychopathology. He must have contributed to medical literature on the general subject of insanity, or some of its phases, or with reports of cases coming under his observation. He must have a fair reading knowledge of at least one foreign language, preferably German. The appointee, in his capacity as clinical director, will have general supervision of all the medi-cal work of the hospital; the supervision and care of the hydrotherapeutic departments, operating room, and the training school for nurses; all transfers of patients from one service to another will be made through him; he will have charge of the clinical records and see that they are uniformly maintained, and be in a position to offer suggestions that recent medical literature may contain along the lines of clinical psychiatry. Applicants must be citizens of the United States, and not over thirty-five years of age on the date of the examination. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for application Form 304 and special form.

Public Health Investigations in Buffalo.—Dr. Edward A. Bowerman, president of the Buffalo Academy of Medicine, was recently empowered to appoint commissions to investigate certain conditions relative to public health. He has named the following: Commission on milk supply—Dr. Irving M. Snow, chairman; Dr. De Witt H. Sherman, Dr. L. Schroeter, Dr. Nelson G. Russell, Dr. Julius H. Potter. Commission on inspection of schools and school children—Dr. P. W. van Peyma, chairman; Dr. Prescott Le Breton, Dr. Frank J. Frey, Dr. Irving P. Lyon, Dr. John R. Gray, Dr. Herman K. DeGroat, Dr. Albert G. Woehnert, Dr. George F. Cott, and Dr. Lee M. Francis. Commission on need of hospitals for contagious diseases—Dr. Julius Ullman, chairman; Dr. Allen A. Jones, Dr. Grover Wende, Dr. DeWitt H. Sherman, Dr. Robert F. Sheehan. Commission on the reporting of tuberculosis—Dr. John H. Pryor, chairman; Dr. DeLancey Rochester, Dr. William Gaertner, Dr. Charles R. Borzilleri, Dr. Norman L. Burnham, Press committee—Dr. Thomas H. McKee, chairman; Dr. Nelson H. Wilson, Dr. P. W. van Peyma, Dr. Irving M. Snow, and Dr. Julius Ullman.

The Forty-fourth Annual Meeting of the American Ophthalmological Society was held at New London, Conn., on Wednesday and Thursday, July 15th and 16th. The following was the programme of the meeting: Sympathetic Ophthalmia, by Dr. E. S. Thomson; Shrinkage of the Eyeball, with Observations on the Processes Underlying Atrophia Bulbi in General, by Dr. W. G. M. Byers; An Unusual Congenital Corneal Formation, by Dr. Burton K. Chance; Recurrent Traumatic Erosion of the Cornea, with report of a case due to Lachrymal Stricture, by Dr. R. J. Curdy; Diffuse Interstitial Keratitis in Acquired Syphilis, by Dr. John T. Carpenter; Thyreoid Extract in Keratitis, by Dr. McCluny Radeliffe; Extraction of Cataract with a Lance Shaped Keratone, by Dr. J. H. Claiborne; Treatment of Immature Cataract, by Major Henry Smith, of the Indian Medical Service, by invitation; An Akempt to Determine the Normal Range of Accommodation at Various Ages, Being a Revision of Donders's Experiments, by Dr. Alexander Duane; Clinical Importance of Relative Accommodation, by Dr. L. Howe; Some Practical Points Regarding the Use of Prism Glasses, by Dr. B. L. Millikin; Strabismus from the Operative Standpoint, by Dr. P. A. Callan; Interpretation and Teleology of Nystagmus, by Dr. Percy Fridenburg; Sudden Obstruction of the Central Artery of the Retina, by Dr. George E. de Schweinitz and Dr. Thomas B. Holloway; Embolism of a Macular Artery and Thrombosis of the Superior and Inferior Arteries in a Case of Embolic Softening of the Examination by Dr. C. M. Hosmer; A Case of Cyanosis Retinæ with Congenital Patent Foramen Ovale and Pulmonary Stenosis, by Dr. H. H. Tyson; Angioma of the Choroid, by Dr. A. Quackenboss, with Pathological Exami-The Forty-fourth Annual Meeting of the American Retinæ with Congenital Patent Foramen Ovale and Pulmonary Stenosis, by Dr. H. H. Tyson; Angioma of the Choroid, by Dr. A. Quackenboss, with Pathological Examination, by Dr. F. H. Verhoeff; A Simplification of De Grandmont's Operation for Ptosis, by Dr. S. Theobald; Report of a Case of Restoration of Sight after one month's Blindness from Glaucoma, by Dr. L. J. Minor; Case of Hæmorrhage from the Cornea in Glaucoma, by Dr. T. R. Pooley; Ocular Affections Associated with Disease of the Sinuses Contiguous to the Orbits, by Dr. S. D. Risley; Report of a Case of Bilateral Retrobulbar Neuritis after Ethmoiditis, by Dr. A. Knapp; Mixed Streptococcus and Pneumococcus Infection of the Orbit and Adjacent Sinuses, by Dr. C. S. Bull; Adenocarcinoma of the Orbit, by Dr. T. R. Pooley; Angioma of the Orbit with Invasion of the Globe along the Bull; Adenocarcinoma of the Orbit, by Dr. T. R. Pooley; Angioma of the Orbit with Invasion of the Globe along the Angioma of the Orbit with Invasion of the Globe along the Giliary Nerves, by Dr. Alexander Quackenboss, with Pathological Examination by Dr. F. H. Verhoeff; The Increasing Importance of Tuberculosis as a Cause of Ocular Discussion of Prenatal Origin, by Dr. G. S. Derby, by invitation; A. Case Presenting Unusual Conditions of Prenatal Origin, by Dr. Burton K. Chance; Sarcoma of the Choroid with Mounted Specimen, by Dr. S. D. Risley; Histological Investigation of a Case of Blepharoconjunctivitis caused by Diplobacillus of Morax-Axenfeld, by Dr. Brown Pusey; Macular Holes, by Dr. C. J. Kipp; Grill Like Keratitis, by Dr. C. J. Kipp; The next meeting will be held in New London. The following officers were elected: President, Dr. S. B. St. John, Hartford, Conn.; secretary, Dr. W. M. Sweet, Philadelphia.

- I. The Diagnostic and Therapeutical Use of Tuberculin, By LAWRASON BROWN.
- Permanent Stenosis of the Ductus Communis from Inflammatory Infiltration or Cicatricial Contraction of a Duodenal Ulcer, By Horace Packard.
- 3. Report of a Case of Melanosarcoma of the Orbit,
 By GUTHRIE McCONNELL and RUDOLPH BURMAN.
- 1. The Diagnostic and Therapeutical Use of Tuberculin.-Brown remarks that until recently it was thought unwise to give tuberculin to any patient who was not constantly under a doctor's immediate supervision, in other words, who was not in a sanatorium or hospital. Recent practical results, however, have shown that this is not necessary, and furthermore, they have shown that ambulant patients and patients at work may be given tuberculin in carefully graded doses, so that not only no harm may accrue, but that the patient may derive great benefit. This means that the former rule that the patient should remain in bed or at rest in a reclining position the day of and the day following injection does not need to be enforced. Brown thinks, however, that where possible, patients should take less exercise the day after the injection of tuberlin. Rise of temperature to 100° F. for more than two hours necessitates rest in bed during that day and the greater part of the next, or until the temperature becomes and stays normal, though practically when accompanied by very slight symptoms the temperature is almost invariably normal the second day even if the patient does not remain in bed. Many medicinal substances have been administered in conjunction with tuberculin, but seem of little value. Various toxines or secondary organisms have been suggested for use in connection with tuberculin but have yet to be thoroughly tested. The effects of repeated doses of tuberculin upon the animal economy have not been thoroughly worked out. The weight seems to be little affected. Changes in the blood have been noted by a number of observers, but the results are still conflicting. The untoward results are very interesting, particularly in regard to the mobilization of the tubercle bacillus. Baldwin was unable to find any evidence that tuberculin, even in large doses, produces this effect. The work of Liebmann, who found many tubercle bacilli in the blood following tuberculin injections, has never been verified, and Brown thinks, can be discredited on account of faulty technique. The sputum and the urine are affected somewhat, but usually only following reactions. An antipyretic effect is unquestionably present in many patients. The results obtained from tuberculin are exceedingly difficult to determine. It must not be forgotten that tuberculin is a powerful toxine, that if administered carelessly it may produce great and irreparable harm. The vast majority of men who have used tuberculin seem to be convinced that it has some beneficial effect. Our author is convinced of this although, he states, he has some difficulty in proving from the results which he has obtained that a markedly bencheral effect is present. He

thinks the present status of tuberculin may be expressed in a few words: Tuberculin when properly given does no harm, may produce no apparent immediate results, but may markedly benefit an individual patient who can follow at the same time the hygienic dietetic treatment while in a health resort or at home or at rest. It may even prove of benefit to those who must continue at work. Small doses and careful increases are most important, and by following these very closely some patients, even in advanced stages, reap great benefit. The immediate and ultimate results of treatment are often improved, few relapses occur, and more patients lose the tubercle bacilli in the sputum.

An Analysis of Four Hundred Cases of Epidemic Meningitis Treated with the Antimeningitis Serum.—Flexner and Jobling have tabulated 395 cases of epidemic meningitis, the total number of recoveries were 295, of deaths 98; twenty-five per cent. of recoveries and twenty-five per cent. of deaths. Tabulated according to the ages of the patients the following is the result obtained:

| Patients. | | Total number. | Re- covered. | Died. | Per cent. of deaths. |
|------------|---------------|------------------|-----------------|-------|-------------------------|
| Under 1 ye | ar | . 22 | , 1 | 1.1 | 50 |
| Retween I | and 2 years. | . IQ | 1.1 | 8 | 42.1 |
| | and 5 years. | | 5.2 | 16 | 23-5 |
| Between 5 | and to years. | . 79 | 70 | () | 11.4 |
| Between 10 | and 20 years. | . 105 | 80 | 24 | 23 8 |
| Over 20 ye | ears | 87 | 64 | -2.3 | 26.4 |
| Age not gi | vcn | . 13 | 7 | - h | 46.1 |

The youngest child which recovered was one month old. The latest case of the disease, in a child under one year of age, which was treated, was in its fourth month when the injections were begun; the child died. The highest mortality was among patients over twenty, which, they think, can be explained in part by the fact that a large number were treated by scattered physicians who had no experience with the serum. If this is not the reason, and adults past twenty are less subject to the action of the serum than younger persons, the fact will of course come out finally; but with one exception-Cincinnati-wherever a series of patients of these ages

has been treated by one observer the percentage of recoveries to deaths has been high-Johns Hopkins Hospital, Cleveland, Belfast (Ireland). The histories of 328 cases were sufficiently explicit to enable them to approximate the periods in which the first serum injection was made. They have arbitrarily chosen the three periods that follow in which to group the cases:

Period of injection Number of of serum. Number of patients. ust to third day...... 121 Fourth to seventh day... 166 Later than seventh day... 167

In spite of the uncertainties surrounding the period of onset of the symptoms which affect the accuracy of the calculation of the period, the beneficial influence of early injection is rendered sufficiently obvious by the table. The period embraced in the last group is highly irrigular, since not a few patients came under treatment when they were in a semichronic or chronic state after many weeks of illness. On the whole, therefore, the outlook even for the latter class of cases is not wholly discouraging, and they are of the opinion that so long as the diplococcus is still present in the meningeal exudate and the mechanical damage to the anatomical structure is not irreparable, the employment of the serum holds out hope of considerable benefit. Closely connected with the rapidity with which the cerebrospinal exudate loses pus cells and returns to a limpid condition is the state of the general leucocytes of the blood. If the inflammatory emigration into the meninges is arrested, then the number of circulating leucocytes should tend rapidly to return to the normal. The facts at hand, based on many counts of the circulating leucocytes before the injections of serum were begun, and afterward at regular intervals, show, as was to be expected, a fall, often very rapid and even critical, in the number of leucocytes in the general blood stream with which the disappearance of the diplococci and the clearing of the spinal exudate are correlated. The indications given by the first series of serum treated patients were to the effect that in the great majority of instances recovery from the disease would be complete. The facts brought out by the far larger series of cases on which this article is based confirm the earlier view which the authors expressed. The number of complications which arose in them was small, and the only persistent defect noted was This lamentable condition occurred in deafness. a few instances only, and it was more often than not noted early in the disease before the serum injections were begun.

4. Nutritive and Neurotic Disturbances of the Hair.-Bulkley and Janeway speak of hirsuties, alopecia, canities, fragilitas cranium, trichorrhexis nodosa, alopecia aveata, and monilithrix. They find that the hair is an active, live portion of the economy, subject to various alterations, dependent on its nutrition and innervation. The well known changes which occur in the hairy coats of animals in ill health, and which have long been recognized as a valuable indication in regard to constitutional treatment, would seem to show that the same might also occur in man. They have found that a certain activity of the hair follicles belongs to a particular period of life, puberty, and a waning of their powers seems to be a natural sign of advancing age. We

have seen that in certain conditions of nutrition and innervation, as after fevers, etc., the hair follicles in some way take on different action, and various disturbances of the hair are observed, and that the effect of profound nervous or mental strain and shock can be evidenced in the hair. Turning to clinical experience, they find that among 15,240 miscellaneous dermatological cases in private practice, a total of 1,129, or over seven per cent., belonged to the group of affections of the hair now under consideration. An analysis of such notes as were kept of them presented many striking features illustrating the points considered in regard to nutritive and neurotic disturbances of the hair. There is great need that the underlying principles be put more in practice; for it is the rarest occurrence to find that patients with the diseases which they have considered have ever previously been interrogated in regard to the matters which have been mentioned, much less that any serious and prolonged attempt has ever been made to rectify the very gross errors of life which have often been discovered. In almost every instance, if a physician has been consulted at all, there has been only some local application given, while in the large majority of cases the trouble has been left to the hairdresser. It is true that the books state in a general way that attention should be directed to the state of the general health, etc., but, as stated, practically everything but the local condition is commonly ignored when these patients apply to the physician for aid.

7. The Smear Method as a Means of the Rapid Diagnosis of Rabies.—Rucker, from his observation of thirteen cases, comes to the conclusion that the smear method is preferable to all other methods because it is much simpler than any other, on ac count of the extreme facility with which the smears may be made and stained, and it is much shorter than any other, inasmuch as the least possible time in which even a poor section could be made and stained is three hours, whereas the time required by the smear method is from fifteen minutes to three hours. In the smear method the Negri bodies appear very distinctly, and their minute structure is brought out very clearly. The smear method is absolutely re-

Diffuse Interstitial Keratitis in Acquired Syphilis.—Davis remarks that diffuse interstitial keratitis may occur as a result of acquired syphilis. It usually occurs as a late secondary sign of the disease or during relapses in the tertiary stage of the general disease. Stephenson gives the average time of development of interstitial keratitis as 10.8 years after the primary sore. Loewinson has reported one case as early as three weeks after the appearance of a primary sore, while Ellett reports a case appearing as late as twenty-three years after the infection. It almost invariably affects but one eye, although there are a few exceptions reported where both eyes were affected. It runs a quicker and lighter course, as a rule, than the cases due to inherited syphilis, and is rarely harmful to the sight. It should be remembered, however, that Griffith has reported one case in which the sight was entirely lost. True salmon patches occur but seldom in these cases. It is difficult to make a clinical diagnost between the sphilitic and the tuberculous

forms of the disease, and even a distinctive pathological diagnosis is not always conclusive. The prognosis is favorable, though it should be somewhat guarded from the fact that sight has been lost entirely in one case.

 Tetanus; with a Report of a Case Treated by Intraspinal Injections of Magnesium Sulphate,
 By W. H. Powers.

2. The Pathogenesis of Pernicious Malaria.-Deaderick remarks that quality of the soil, in the sense so aptly employed by Homem, as a factor in the pathogenesis of pernicious malaria, has probably not received the attention it deserves. This influence in many instances doubtless not only induces the attack but determines its type. Organs or systems enfeebled by antecedent ailments are apt to play the title rôle in the pernicious tragedy. Thus algid and choleraic attacks may be associated with a history of intestinal catarrh; the comatose and delirious cases with a history of abuse of alcohol; the convulsive with epilepsy, etc. It is not improbable that some cases of dysenteric, cardialgic, syncopal, tetanic, cataleptic, paralytic, pneumonic, pleuritic, gastralgic, and other forms described by the older writers may be similarly explained. Malarial subjects, who are much exposed to the heat of the sun, are liable to be stricken with pernicious fever, especially of the cerebral type. This danger is enhanced if to the solar heat are added fatigue, deficient or improper food, or other hardships. Certain psychic states have causative significance. In addition to these four principal factors, congestion of viscera and parasitic obstruction of the hepatic capillaries have been regarded as important. It is probable that they have little influence. In the comatose variety any of the four chief agents may take part; idiosyncrasy and external influences may unite with any of the other factors; an extraordinary number of parasites in the general circulation without accumulation in the brain is productive of coma probably because of the toxine. Ewing says that the majority of cases of comatose malaria coming to autopsy do not show a massing of parasites in the brain. He attributes these cases to general toxæmia. However a study of the autopsy records of Marchiafava and Bignami shows that in a great majority of their fatal comatose cases the parasites were markedly localized in the brain. Davidson and Ruge believe that almost always the cerebral capillaries are found filled with parasites in those who have died with coma. Other pernicious cerebral forms are usually associated with parasitic localizations. The algid variety, while possibly sometimes dependent on toxæmia, is usually due to a massing of the parasites in the gastrointestinal mucosa. This is explained by Davidson as follows: "Experiments show that the alimentary tract is in

closer connection with the cardioinhibitory centre than other parts of the body, and that irritation of this tract, if sufficiently powerful, will produce cardiac inhibition, with pallor of the surface and accumulation of the blood in the abdominal vessels. That the intestinal canal is the centre of mischief in this form of pernicious attack will appear all the more probable if we observe the character of the disturbances so frequently associated with the algid condition—the cardialgic pain, the choleraic vomiting and purging, and the dysenteric discharges." Other forms of pernicious malaria are probably due to localization or to complications.

Tetanus; with a Report of a Case Treated by Intraspinal Injections of Magnesium Sulphate.—Powers describes the method of treatment: The patient was chloroformed, turned on the side, with the body flexed. A small area over the lumbar vertebræ was sterilized, the line at the upper margin of innominate bones ascertained, and a little to one side of the spinous process a small skin incision was made. An ordinary solid metal 10 c.c. syringe was filled with a 25 per cent. solution of sterilized magnesium sulphate; a four inch needle was used. After the needle had been inserted approximately to the proper place the syringe was detached. As no spinal fluid appeared, it required a little further manipulation of the needle before the cavity was penetrated. About 2 c.c. of spinal fluid was allowed to flow, then the syringe was attached and 2 c.c. of magnesium solution was injected slowly. A prescription was written for a combination of chloral, bromide, and morphine, also for a saturated solution of magnesium sulphate. Owing to the patient being cared for by negroes, no careful account of symptoms can be given, and the medicine was also given sporadically. On the third day 10 c.c. of tetanus antitoxine was injected deep into the thigh muscles along the supposed course of the bullet. At this time the patient was considerably worse as regards pulse and respiration, although the convulsions were not so severe as when first seen. The next day another spinal injection of magnesium sulphate was given in slightly larger dose, and three hours after this the patient was absolutely relaxed and complained of a "splitting" headache. This injection had a marked effect as late as forty-eight hours. Six days after coming to town the man was removed to the hospital as a charity patient. At this time he was absolutely rigid, but the general conditions had improved, and the convulsions were not so frequent or severe. From this on his condition gradually improved under the use of chloral and bromide, and salts by mouth, until sixteen days after his arrival in town, when he was able to walk about

5. Tetany in the Adult, By J. A. GIBB

 Mucous Colitis and its Relationship to Appendicitis and Pericolitis, with Remarks upon its Treatment by Irrigation (Plombière's Bath), By A. MANNILE.

r. Pulmonary Tuberculosis .- Whitla, in his Cavendish lecture, discusses the ætiology of pulmonary tuberculosis, and gives the details and results of experiments which go to show that the intestinal route plays a far more important rôle in the production of human pulmonary tuberculosis than has been hitherto recognized. The lungs of guinea pigs, fed on an emulsion of India ink for four days, are engorged with carbon; the same thing happens when the emulsion is injected into the peritoneal cavity. The tubercle bacillus passes through the intestinal mucosa like the fine particles of India ink, without causing any lesion or leaving any local evidence of its point of entrance. Though we still are hardly justified in assuming that pulmonary tuberculosis never occurs from the inhalation of dried sputum dust or from the breathing of the spray ejected at the moment of coughing, it appears to be conclusively proved that the alimentary tract is a frequent portal of entry for the tubercle bacillus; that this event is especially frequent in children, and that the milk of tuberculous cows is the common source in these cases. Probably at no distant date the contention of Calmette will be accepted that in the immense majority of cases pulmonary tubercu-losis is not contracted by inhalation, but, as taught by von Behring, the germs enter through the intestinal tract. Future research will have to explain how in China, where practically no bovine milk is used, tuberculosis is everywhere prevalent among

2, 3. Congenital Pyloric Stenosis in the Adult. -Russell reports three cases of congenital simple stenosis of the pylorus, occurring in individuals aged thirty-four, forty-two, and fifty-one years, respectively. There is usually a long history of stomach trouble, and the patient has learned to be careful of the character and quantity and intervals between the meals. There may be a history of supposed "bilious attacks" dating back to childhood. The symptoms are those of stomach dilatation or of gastric dyspepsia, vomiting only occurring in the more severe attacks. The attacks tend to become intensified as they are repeated, and something eventually happens, often not till life is fairly advanced, which brings out the pyloric difficulty and leads to all the symptoms of pronounced pyloric obstruction. The diagnosis in the case of simple stenosis is determined by the existence of pyloric difficulty, the character and duration of the history, the absence of permanent pyloric thickening, the presence of free hydrochloric acid in the stomach contents, the exclusion of ulcer, of malignancy at the pylorus, and of a history that would fit in with cicatrix from previous ulceration. When there is permanent thickening, the benign causes, ulcer excluded, are congenital hypertrophic stenosis, and cicatrix from healed ulcer. Once the possibility of congenital stenosis occurring in the adult enters the clinical field of vision, its distinctive diagnosis is not so very difficult. The treatment may be summed up as follows: 1. Control excessive secretions. 2. Reduce pyloric irritability. 3. Increase the muscular activity of the stomach wall.—Maylard reports twelve cases of adult congenital pyloric stenosis, and

reaches the following conclusions: 1. That there exists an abnormal condition of the pyloric aperture, of probably congenital origin, which consists in an undue narrowing of the orifice, varying anything between two and ten or twelve millimetres. 2. That the condition is more frequently met with in women than in men, and that the age at which the symptoms first appear depends upon the narrowness of the aperture and the general physical or constitutional condition of the patient. 3. That the narrowing leads to a more or less chronic condition of indigestion manifested in various forms, and often mistaken for chronic ulceration or chronic gastric catarrh; that in the early stages relief is afforded by careful and strict attention to diet, but that any attempt to return to normal feeding causes a recrudescence of indigestion. The attacks of gastric discomfort are at first separated by considerable intervals, but these lessen in length as time goes on. 4. That when the patient is advanced in life and shows marked general debility operation will prove of doubtful value. 5. That if regulation of the diet fails to afford relief, pyloroplasty or Finney's operation-preferably the former-should be practised.

Tetany.—Gibb reports two cases of tetany in adults, and states that there can be no doubt that the condition is due to some toxine absorbed from the alimentary canal. Absorption is suggested by the fact that tetany occurs in association with gastric dilatation. Tetany in children occurs in association with rickets, of which disease gastric catarrh is a constant feature. In children the nervous system is undeveloped, and thus there is lack of cerebral control. The posttetany irritability of children is marked, and only very slight causes are required to bring on a fresh attack.

6. Mucous Colitis .- Mantle embraces in the term "mucous colitis" that morbid condition of the mucous membrane of the colon in which the predominating feature is the passing of mucus in the stools. Constipation is a prominent feature in the great majority of the cases. The importance of early treatment cannot be overestimated. antiseptic treatment by the mouth (sale), aphthol, etc.), with strict dieting, may cure a mile case, yet better and more lasting results can be obtained if the bowel is washed out just as is done in the case of the stomach when a similar condition of chronic catarrh and dilatation exists. Surgically the cæcum has been opened, and the motions allowed to pass through the artificial anus for some weeks, so as to give the colon rest and to permit of its being washed out with antiseptic solutions. The appendix has been made use of in a similar way, by fixing it to the abdomen, opening its distal end and inserting a rubber catheter through which irrigation takes place. Treatment by irrigation of the colon, as carried out at Plombières and Harrowgate, gives excellent results. It consists of irrigation of the ounces of alkaline sulphur water at a low pressure are used. After the interval douche follows a warm ing upon the wall of the abdomen from a large nozthe colon. Attention, on the patient's part, to modtle to the cold extremities, and avoidance of exposure to undue cold will give the greatest comfort, and by attracting blood from the splanchnic area to the periphery relieve the affected bowel. Care in diet, avoiding all articles of food which may irritate the mucous membrane, must be strictly en-

The Infant in the School Medical Examination,

By A. D. EDWARDS. A Visit to Professor Wertheim's Clinique in Vienna, By A. H. N. Lewers.

Errors in Metabolism.—Garrod, in the second of his Croonian lectures, takes up the subject of alkaptonuria. When freshly passed the urine of an alkaptonuric is usually normal in tint, but it quickly begins to darken in contact with the air, and finally becomes actually black. Alkalinity of reaction greatly hastens the change. On heating the urine with Fehling's solution a deep brown color develops and copious reduction occurs. The most striking reaction is observed when a dilute solution of ferric chloride is allowed to fall drop by drop into the urine. The fall of each drop is followed by the appearance of a deep blue color which lasts but for a moment. Alkaptonuria is a very rare phenomenon. In the great majority of cases it is present from birth, and persists throughout life giving rise to no symptoms save occasional dysuria with undue frequency of micturition. A few alkaptonurics are attacked in later life with the condition known as ochronosis, the essential feature of which is the staining of the cartilaginous structures of an inky blackness. Surface or subsurface pigmentation is sometimes present and renders possible the recognition of the condition in living subjects. The blackened aural cartilages may show through the skin, and black flecks appear upon the conjunctivæ, the skin of the face, and the knuckles.

4. Arteriosclerosis.—Gubb discusses the premonitory signs of arteriosclerosis, and states that the tendency to the disease is markedly influenced by heredity, although it can be acquired by certain habits of life. Many of the subjects are the offspring of gouty or arthritic parents, and in these the premonitory signs of the degeneration may be observed quite early in life in the form of attacks of nose bleed, migraine, premature baldness, etc. There is a slackening of the intellectual powers, and the subject is easily fatigued. There is a peculiar sensitiveness to alcohol and tobacco, even in reduced quantities. Irritability of temper is fairly constant. More or less persistent headache is a common early feature. It is apt to be caused or intensified by intellectual effort, by alcohol, or by excitement. Sensory disturbances, in the form of

neuralgia or giddiness, are fairly common. The same is true of disturbances of sleep, but true insomnia is rare. Mental depression is always present to some degree. Exaggerated arterial tension, with a small, hard, thready, but regular pulse, is also a premonitory sign of arteriosclerosis-indeed some authorities hold that actual changes in the arterial walls are preceded by prolonged exposure to the illeffects of persistent high pressure, such hypertension being due to spasmodic contraction of the arterioles probably dependent on toxic irritation of the vasomotor system.

5. Shock and Peritonism.-Walton summarises the treatment of shock and peritonism, as follows: In shock, which is due to exhaustion of the nervous centres, no form of stimulant should be given before or during an operation. When signs of shock begin to develop, as shown by a fall in pressure, hypodermic injections of ergot should be given. If the fall in blood pressure continues a vein should be opened and the patient infused; for this purpose one drachm of adrenalin to one pint of saline solution should be used. If the operation is an abdominal one, saline solution may be poured into the abdominal cavity. During operation cocaine should be injected into any large herve before it is divided, and exposure or handling of organs and viscera should be avoided as much as possible. When the patient is returned to bed a quarter of a grain of morphine should be given, and the foot of the bed raised about two feet. Ergot should again be given subcutaneously, and saline solution and suprarenal extract injected continuously into the rectum. In peritonism, or acute paralysis of the intestines, due to some toxic condition present within the peritonæum, the intestines should be drained as fully as possible during the course of the operation undertaken for the relief of the local condition. In all other conditions no operation is called for, and since the state of the intestines depends upon the exhaustion of the nerve centres, any form of stimulation is only likely to do harm. Immediately after operation, injection of 0.01 grain of eserine salicylate should be given, and continued every four hours until six doses are given. If no movement of the bowels occurs next day a turpentine enema may be given. In conclusion then, it may be stated that the effects of any severe operation upon the autonomic nervous system consists of an exhaustion of its centres, both central and local, and that any treatment must aim at procuring rest of these centres. Since in man exhaustion always occurs first in the nervous system treatment of the symptoms should aim at stimulating the local organs so that they may act alone until such time as the centres are again able to undertake the control.

LA PRESSE MEDICALE

Colloidal Silver in the Infectious Diseases,

By A. NETTER Numerical Atrophy Resulting from Childhood, Burns during By A. Daniel. Ochronosis and Alkaptonuria, By R. ROMME.

Colloidal Silver in the Infectious Diseases. -Netter urges the useful properties of collargol and asserts that the bactericide properties of the colloidal silver produced chemically and known as collargol are not better than those of the compound produced by Bredig's electric method and known as electrargol or ultrargol. The objections which have been raised against the latter are, he states, without foundation.

2. Numerical Atrophy from Burns during Childhood.-Daniel records the case of a boy burned at the age of three years on the left side of the face. At the age of twenty-two he had facial hemiatrophy from arrest of development, atrophy of the bony structure and of the muscles of the face, diminution in the size of the left upper lid and of the eyeball, with contraction of the pupil, atrophy of the teeth, rarefaction of the hair, and reduction in the size of the pinna of the left ear. After a critical historical study, in which he brings out the fact that in these cases the atrophy is diffuse and generalized, not partial, circumscribed, nor selective of a group of muscles, the writer passes on to consider the pathogeny of the condition and the several hypotheses that have been advanced. He considers the hypothesis advanced by Klippel to be the most plausible and the most scientific, viz., that the arrests of development caused by burns belong to the general class known as numerical atrophies, a term introduced in 1893 to denote an atrophy in which there is not only a diminution in the volume of the part, but also an actual decrease in the number of its elements, some of them having been destroyed. He then presents the results of his experimental studies, in which he shows that the two histological processes present in experimental numerical atrophy and the numerical atrophy of human beings are identical.

2. Some Faults Ascribed to Anæsthesia with Ethyl Chloride, By L. Camus.
3. A New Theory of Surgical Shock, By J. P. Langlois.

2. Anæsthesia with Ethyl Chloride.—Camus concludes that for an anæsthesia of brief duration the use of ethyl chloride is the method of choice, but that this method cannot avoid minor postanæsthetic accidents in every case any more than any other, because these are sometimes attributable to the temperament of the patient, sometimes to the conditions of the operation. But in spite of the minor troubles which may present themselves on awakening, the patients do not maintain a bad recollection of ethyl chloride, and those who have had to submit to repeated operations prefer this method of anæs-

3. A New Theory of Surgical Shock .- Langlois discusses the theory ascribed by him to Henderson, of the Yale Medical School, that surgical shock is provoked by a diminution in the proportion of carbonic acid in the blood, and that the prophylaxis of shock consists essentially of preventing an extensive loss of this gas from the blood.

12. Concerning the Present Position of Endonasal Surgery, By FINDER.

4. Nature of the Leuchæmic Pathological Process and its Treatment.—Grawitz has come to the following conclusions as the result of his observations: I, The chances of recovery are more favorable when the patients can be kept in bed, carefully nourished, and given arsenic at the same time, than when they are treated ambulatorily by means of the x rays. The technique of the exposures plays undoubtedly an important part in the efficacy of the x rays. The length of the exposures and their frequency are not less important. A case is cited in which a woman with mixed celled leuchæmia was treated for a year with short exposures without effect, and then cured in a few weeks in the hospital. 2, The duration of the disease is of great importance, for even though an improvement may be brought about in leuchæmia which has lasted for years by a diminution of the leucocytes, it is evident that in such cases the pathological deviation of the cell formation in the blood making organs has become so firmly rooted that a return of the tissues to their normal function can no longer be looked for. In these cases one can observe the working of the leucolysis by the x rays, but not the plastic regulation. It is, therefore, imperative that the diagnosis of this disease should be made at as early a period as possible. It should not happen to-day that swellings of the spleen and of the lymphatic glands should be observed and treated for a year without examination of the blood, and so the patients lose their frequently good chance of recovery. 3, The origin of the disease is not of less importance, and the prognosis is unfavorable in acute cases associated with septic symptoms, as well as in those associated with chronic inflammation of the lymphatic apparatus, which indicates a persistent and nonremovable irritation of the blood making organs, so that a leucolysis, but not a true return to normal function, can be obtained. 4, The age of the patients plays a part in so far that, while improvement in the general condition may be obtained in elderly people, such improvement does not last, and old are can to have a similar effect to long standings in sanger people in making a return of the tissue to its normal function impossible. 5, The condition of the blood is not to be excluded in considering the prognosis, for the lymphoid type may recover, though formerly this was doubted. A case of lymphoid condition of the blood, with externally demonstrable enlargement of the spleen without glandular tumors has no worse a chance than one with a mixed cell condition of the blood. But if the peripheral lymphatic glands are greatly swollen the prognosis appears to be bad.

5. Artificial Respiration of Adults.-Meyer and Löwy give an excellent anatomical description of the modus operandi of Sylvester's method of

artificial respiration.

10. Carbonic Acid Snow in the Treatment of Skin Diseases. - Pusey considers freezing the skin for from ten to thirty seconds with carbon dioxide to be an efficient method of treatment for pigmented and vascular nævi, warts, and senile keratoses. In superficial epitheliomatas he has had brilliant results; in deep tumors he has not employed the method, but thinks it might be of use in many. He failed to get benefit in lupus erythematodes or lupus vulgaris.

13. Epidemic of Cerebrospinal Meningitis in Pfalz in the

Spring of 1007 (concluded). By H 14. François Rabelais on the Duties of the Physician.

Effect of Stasis Hyperæmia in Animal Experiments.—Frangenheim states, as the result of his experiments that the stasis hyperæmia produced had little or no bactericidal effect, that infections were not prevented by previous or immediate stasis, and that all cases of suppuration in the bone medulla and the majority of the cases of suppurations in the joints were unfavorably influenced by the stasis. A characteristic property of the stasis hyperæmia which is produced by stasis and by suction is the increased formation of pus and the leaving behind of infiltrates about the purulent foci.

4. Cytological Conditions in the Conjunctival Reaction to Tuberculin.—Dietschy asserts to have demonstrated that the microscopical examination of the secretion from the eye during the conjunctival reaction to tuberculin presents a form of leucocytes the fluctuation of which in the course of the reaction are typical and agree with the conditions present in other acute inflammations. No value can be placed on the occasional presence of polynuclear leucocytes,

because such are to be found sometimes in the conjunctival secretion of eyes which have not been treated in this manner. Tuberculin seems to call forth no chemotatic leucocytosis. The conjunctival secretion may present these changes in many persons with tuberculosis even when no reaction can be detected macroscopically, hence this means the ophthalmocytodiagnosis is a means whereby the value of the ordinary conjunctival reaction is enhanced

5. Bang's Method of Titration of Sugar.-Dilg declares that for solutions which contain no other reducible substance except sugar Bang's method is preeminently satisfactory. Also in the examination of urine it appears, in spite of its limitations, to be a desirable advance for the practitioner.

6. Hebeosteotomy and Premature Labor in Private Houses .- Müller considers hebeosteotomy, section of the pubic bone, to be an operation which should be performed in private houses only by experienced surgeons, and that in the majority of cases induced premature labor is safer for both the mother and the child.

- 8. Ruptures of the Rectum.—Burkhardt reports a case of spontaneous rupture of the rectum in a young man, seventeen years of age. Laparotomy was performed, the laceration sewed up, and the patient recovered. The cause of the rupture was obscure. It was a case of rupture during defæcation of a healthy rectum in a healthy young
- 12. Cure of a Perforated Ulcer of the Stomach by Opening an Intraperitoneal Abscess.-Weimann reports the case of a man, fifty-three years of age, who had suffered for eleven years from ulcer of the stomach, and finally was attacked with an abscess in the epigastric region. When opened this abscess was found to communicate with the stomach through a perforated ulcer, which healed rapidly after the operation.

- 10. Congenital Unilateral Absence of the Urogenital System and its Relation to the Development of the Wolffian and Müllerian Ducts, By H. E. Radasch.
- 1. Congenital Pyloric Spasm and Congenital Hypertrophic Stenosis of the Pylorus in Infancy. -Koplik considers, under the head of treatment, feeding, mechanical means of therapy, drugs, and operative measures. Feeding is the most important element in treatment. Breast feeding is ideal and should be given at long intervals with short nursings. If this is not available one of the artificial foods containing a minimum of fat may be selected. Small amounts must be given at proper intervals.

Mechanical therapy will include hot poultices, dry heat, stomach washing, and enteroclysis. Stomach washing is not advised; enemas of saline solution may be given several times daily. As to drugs, opiates in some form are advised by many writers, but are not favored by the writer, neither is sodium citrate, nor sodium and pancreatin. Operations, if performed at all, require great technical skill, great dexterity, and great rapidity. The mortality in any event is large. If posterior gastroenterostomy is performed, the exclusion of a portion of the intestinal tract which is necessitated is likely to be harm-Anæmia and rhachitis may be consequences, and respiratory apnœa and indigestion from narrowing of the artificial opening in the stomach have been reported.

- 2. The Therapeutics of Selfrepair.-Meltzer thinks the conception justifiable that the living organism is comparable to a complex human made machine. The comparison is not quite just in that our knowledge of the living organism is still very imperfect, hence our therapeutics is still defective. Still, it is marvelous that the results of ignorant meddling with this sensitive organism have been so lacking in seriousness. It is now known for a fact that the living organism has automatic arrangements for selfrepair. Of the rational and empirical methods of treatment the former leads to inactivity; the latter, while active, is unreliable as to results. Immunity has now become a third method of treatment; it embraces the study and use of antitoxines, and is a field full of promise. The signs of inflammation are now considered factors in selfrepair; witness the method of venous hyperæmia. Artificial leucocytosis is another method of utilizing the body forces to combat disease. The great object in therapeutics to-day is to utilize the methods which Nature uses, improving upon them if possible. Pathological therapeutics promises to be the most efficient method of studying therapy.
- 4. Cardiac Arrhythmia.—Norris states that to explain satisfactorily and study the different forms of arrhythmia we must classify and group them according to the five fundamental properties of the heart muscle. The myogenic theory of cardiac activity is practically necessitated as a working basis. The first type of pulse irregularity in this study is juvenile arrhythmia, affecting the diastolic period, the pulse slowing down after fever, especially between the ages of eight and fifteen. The second is extrasystole, with an intermittent pulse from irritation of the ventricle, from heart block, or from diminished excitability. The third is perpetual arrhythmia, in which no regular rhythm can be made out for weeks or months. The fourth is heart block, which are due to depression of conductivity, with the dropping of the ventricular beat or complete dissociation of the auriculoventricular rhythm. The fifth form is that of depression of contractility, the so called pulsus alterans. Arrhythmia of muscular origin is more serious than that which is due to nervous causes. The time and cause of it will greatly modify or influence the opinion as to its seriousness.
- 5. Peculiarities of the Symptomatology of Rheumatism in Children.—Dunn divides the cases into the following types: 1. The mild arthritic, with slight, brief fever, and mild brief joint symp-

toms. 2. The severe arthritic in older children, with severe polyarthritis. 3. The latent, with fever at the onset, and with subsequent mild or severe cardiac or arthritic symptoms. 4. Mild primary endocarditis, with fever, dyspnœa, palpitation, præcordial pain, and slight joint symptoms. 5. Severe primary endocarditis, with fever and cardiac incompetency. If recovery takes place it is very gradual. 6. Mild pericarditis, with fever and præcordial pain. course is prolonged, and is accompanied with endocardial murmurs. 7. Severe pericarditis, with high, obstinate fever, præcordial pain, and effusion. Cardiac insufficiency with severe symptoms will be followed by slow recovery or by death from cardiac weakness

7. Myelogenous Leuchæmia and its Treatment with X Rays .- Harris thinks this is a malignant neoplastic disease. Its onset is insidious, and it is usually fatal. It is sometimes favorably influenced by intercurrent disease, and it is usually influenced favorably by x rays. In favor of its malignancy is the fact that in many of the organs are masses of cells identical with those of bone marrow, which are foreign to the organs involved, and are apparently metastases. In the author's series of cases the average number of leucocytes was 312,000; that of the red cells was 2,860,000. The average hæmaglobin content was fifty per cent. Under the influence of the x rays the number of the leucocytes was reduced. The diagnosis in the author's cases was easy, as there was a typical blood picture and the spleen was enlarged. Arsenic was administered as a tonic, and the x rays were used three times weekly for three months, subsequently every five days for two months. As the blood picture improved, and the condition of the patient became more favorable, the treatment was given at still longer intervals.

7. Nitrous Oxide with Oxygen as an Anæsthetic Agent. Gwathmey gives the following as the ideal routine administration: In addition to the monal preparation the patient's nerves should be controlled by previous medication in either of the two following ways: (a) A suitable dose of morphur according to the age and condition of the patient, or (b) an enema of seven ounces of saline solution and one of whiskey one half hour before the operation. The patient will then come to the table in a suitable frame of mind. The narcosis should be commenced with nitrous oxide and oxygen or nitrous oxide and air, and continued until full, surgical anæsthesia is reached with this agent, and then the ether chamber turned on gradually and slowly. In this way there will be no swallowing in the first five minutes. The method of administration should now be changed to the closed inhaler, and the anæsthesia deepened by rebreathing. This should be continued until the whole system has been thoroughly stimulated by the ether. A change should now be made to warm chloroform, given either by the vapor method or drop by drop. This change to chloroform should be made when the patient is only lightly under the ether. Care must be taken not to allow the patient to come out sufficiently to exhibit any rigidity of the muscles, on the other hand, not to deepen the narcosis unnecessarily. As the operation is drawing to a close a warm saline enema should be given and the anæsthetic should be so lightened that the patient will exhibit signs of consciousness as the bandages are being applied. Place the patient in bed with as little jolting and jarring as possible. Darken the room and allow the patient to sleep until natural awakening occurs. The enema should be repeated every few hours as required, that is, until the patient shows some effects of its administration.

4. The Serous Coat of Bloodvessels Compared with the Peritonæum .- Morris thinks the most important part of the new surgical work with bloodvessels, especially with aneurysm, depends upon the similarity of the serous coat of bloodvessels to the peritonæum. Like the latter, the former throw out lymph for purposes of repair. Irritated surfaces in apposition adhere, and septic processes in the serous coat cause changes similar to those which occur in the peritonaum. Torsion of bloodvessels also causes such quick plastic occlusion that arteries of

the third class may be thus treated in place of by ligation. Aneurysm treated by digital pressure, by the introduction of coils of wire, or by electric needles causes exudation of lymph from the serous coats, followed by adhesion of opposed surfaces. The new work in suturing bloodvessels depends for its safety upon the prompt plastic repair of the serous coats. A warning from work upon the peritonæum should teach, however, that in suturing bloodvessels in general, a weak point will be left at the site of the slightest depression of the serous coat unless the other coats are treated in a way to fortify the weak point.

6. Operation for Nonpenetrating Intracranial Trauma.-Hartwell analyzes seven cases and reaches the following conclusions: I. Only in cases of isolated injury affecting the sensorimotor area can a positive focal diagnosis be made. 2. All grades of brain injury may be found in different parts of the same brain. 3. A general concussion may be followed by secondary changes in the circulation, which, if not relieved, will produce pressure and death. 4. A pure decompressing operation is indicated in two conditions, (a) for the relief of pressure due to inaccessible hæmorrhage, and (b) to relieve the pressure arising from traumatic ædema of the brain. 5. Operation done without a very definite object in view, which object is based on careful diagnosis, is apt to be more harmful than helpful. 6. The entire subject is fraught with manifold difficulties, and the brain surgeon should strive to become a practical neurologist in organic lesions.

7. Splenectomy.—Johnston quotes Vulpius as to the results of this operation, as follows: I. Extirpation of the spleen produces a transitory decrease in the number of red and an increase in the number of white corpuscles. 2. The thyreoid gland cannot vicariously assume the function of the spleen. 3. The lymphatic glands and the bone marrow show an increased blood forming activity after removal of the spleen. 4. The regeneration of the blood after loss of blood is probably less rapid in individuals from whom the spleen has been removed. The author collected 708 operations, with 514 recoveries. In the period from 1900 to 1908 there were 355 splenectomies, with 289 recoveries and a mortality of 18.5 per cent., against 27.4 per cent. for the entire series. Excluding splenectomies for traumatisms, there remain 242, with 210 recoveries. The contraindication to splenectomy in leuchæmia would exclude seven additional cases, leaving the mortality for the remaining 235 cases only 11.5 per cent.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

Section in General Medicine.

Meeting of March 17, 1908.

Dr. HERBERT S. CARTER in the Chair.

Cardiac Complications in Pulmonary Tuberculosis.—Dr. Lawrason Brown, of Saranac Lake, N. Y., read this paper. He considered the subject from two standpoints, the heart itself not diseased and the heart itself diseased.

I. The heart itself not diseased. The position of this organ in patients with pulmonary tuberculosis

depended, he said, directly upon the pathological changes that had taken place in the lungs. Adhesions often prevented displacement of the heart where one might be led to expect it. In right apical lesions of some standing the right border of the absolute cardiac dulness was found three quarters to one inch or more to the right, or about at the middle of the sternum. When there was extensive cavity formation on the right, when pneumothorax or effusion supervened upon the left, when the right lung was the seat of fibrosis consecutive to pulmonary tuberculosis, or, as some affirmed, to pleurisy, the heart might be found entirely upon the right side. In an interesting case of pneumothorax from rupture of the wall of a cavity in the lower part of the left upper lobe, the heart was found gradually forced over toward the right side a number of times, but it always returned when a needle was introduced and the air allowed to escape. Pulmonary tuberculosis was probably by far the most frequent cause of noncongenital dextrocardia, but this usually developed only when the left lung was slightly affected and was not bound down by pleuritic adhesions. Contraction of the left lung or pneumothorax upon the right side might so greatly displace the heart that the point of maximum impulse was beyond the left anterior axillary line. Many theories had been advanced to account for the smallness of the heart which undoubtedly existed in a number of patients who had died of pulmonary tuberculosis. Post mortem observations were not entirely satisfactory for the solution of this problem. Rueter, in 1884, in 250 autopsies on patients with pulmonary tuberculosis, found a small heart in twenty-nine per cent. of the men and in fifty-six per cent. of the women. During the past year Mendl and Selig had stated that the heart was small in comparison with the body. If, as Krehl believed, the same amount of blood was driven through the lungs until the pulmonary vessels were reduced three quarters, it was readily seen that the remaining vessels must increase in size or dilate, or pressure in the pulmonary artery would increase, the right ventricle undergo hypertrophy, and the second sound at the pulmonic area become accentuated. Few observations indicating enlargement of the heart in pulmonary tuberculosis had been made until recently, and some of the authors had attributed the hypertrophy in many cases to alcohol. Palhier believed that hypertrophy occurred only when pathological changes were found elsewhere in the body. In 200 autopsies at the Phipps Institute hypertrophy was present thirteen times, six times of the left ventricle, two of the right, and five of both. Clinical statistics bearing upon the size of the heart were meagre. The diagnosis of enlargement of the heart in far advanced stages, where fibrosis and contraction or emphysema were often pronounced, must rest upon the accentuation of the pulmonic second sound and increased epigastric pulsation, or, indeed, the use of the x ray. Emerson believed that if the general nutrition was maintained or was increasing, the general blood pressure remaining normal, and if there was rapid action of the heart with accentuation of the second pulmonic sound, cardiac hypertrophy was in all probability taking place, even though not evident in clinical examination. Laennec, Louis, and others had noted dilatation of the heart to be exceptional;

it had been found more in acute types of the disease (Brun), especially when they occurred in patients with chronic fibroid changes. In acute miliary tuberculosis of the lungs dilatation and hypertrophy of the right ventricles were not rare, and were essentially mechanical results, due to the impeded pulmonary circulation. Sequer, in 271 autopsies, had found it present twenty-one times in patients with fibroid, seven times in patients with ulcerative forms. At the Phipps Institute dilatation of the right heart had been noted clinically in nine per cent. of 1,491 patients, and at autopsy in twenty-four per cent. of 200 cases. According to Norris, it occurred clinically in thirty-two per cent., at autopsy in twenty-one per cent. of patients with pulmonary tuberculosis. Dilatation of the right side was often accompanied with hypertrophy of the right ventricle, which Jaccoud believed was favorable. The area of cardiac dulness was rarely changed in 1,289 patients at the Adirondack Cottage Sanatorium unless some valvular disease was present. Careful auscultation of the heart revealed in a large proportion of the cases of pulmonary tuberculosis some deviation from the normal state. A study of the hearts of 1,289 patients at the Adirondack Cottage Sanatorium showed that sixty-five per cent. presented some slight deviation. In seventyfive per cent. of the cases the heart sounds were found of normal relative intensity. A weakened first sound was rather frequent in well advanced stages and is often more pronounced during acute attacks. Functional murmurs were present in six per cent. of these 1,289 cases and in 2.6 per cent. of 639 at the Phipps Institute, but the latter were in much more advanced stages, when such murmurs would seem more likely to occur. A systolic whiff due to compression of a cavity during systole was not very rare, and murmurs might be produced in cavities by the systolic distention of a large vessel or of an aneurysm. Reduplication of the heart sounds had rarely been noted, occurring but in one per cent. of the 1,289 cases. Irregularity of the heart's action and a skip of the beat were infrequent in the early stages. The pulse in tuberculosis was a very valuable guide, both for prognostic purposes and in the regulation of exercise. The majority of the patients had at first a slightly increased pulse rate (90 to 100), even when apyretic and frequently when at rest in bed. The cause of the increased frequency was still unsettled. Inflammation of the vagus, with a fall in blood pressure, irritation of the sympathetic, increased irritability of the cardiac ganglia or muscle fibres, myocarditis, anæmia, and dyspepsia had all been suggested as factors. most probable cause, especially in incipient cases, was a weakening of the cardiac muscle and its nervous control due to the tuberculous toxine. blood pressure in many cases of pulmonary tuberculosis was lowered from the very onset, and some had held that defective tension was present in the predisposed. Palpitation occurred in twenty-one per cent. of the 1,289 patients, but it was a rare thing for patients to complain of this symptom in the

2. The large treef diseased Heart disease detering during pulmonary tuberculosis might be trend, as sider of frequency, in the pericardium, the ordered in a the myocardium. Nontuberculous

changes in the myocardium were not infrequent at autopsy, but difficult to detect clinically. They were very rarely tuberculous in nature, and consisted of fatty degeneration, fragmentation of the myocardium, and hypertrophy of the muscle nuclei. Fatty degeneration might follow this muscular atrophy, but unless the pericardium also was affected, these changes often passed undetected. When, however, cyanosis, œdema, dyspnœa, and a frequent and irregular, small pulse occurred, such changes were very probable. Adynamia was not common, and occurred usually only late in fibrosis. Kidd believed that attacks resembling angina pectoris were only coincidences. The great increase in weight which some patients who were kept perfectly quiet exhibited must at times affect the heart. Tuberculosis of the myocardium was very rare, being observed about once in a thousand autopsies of tuberculous persons. It had little clinical significance and was practically never diagnosticated except post mortem. It was said to occur most frequently in miliary tuberculosis, less often as large solitary tubercules, and more rarely still as a diffuse tuberculous fibrosis without caseation. These changes seldom produced functional disturbances. The disease usually extended by direct continuity from the pericardium or endocardium into the myocardium. The pericardium was said to be more frequently attacked in tuberculosis than the endocardium or myocardium. The symptoms were frequently very obscure and often overlooked. In 7,646 cases of pulmonary tuberculosis, Norris found only thirty-one instances of pericarditis. Tuberculosis ranked next to rheumatism in the ætiology of pericarditis. A tuberculous pulmonary cavity might in very rare instances perforate into the pericardium, producing pneumopericarditis. The occurrence of pericarditis naturally aggravated the symptoms of tuberculosis, and the prognosis was unfavorable.

Clinically, endocarditis was found associated with pulmonary tuberculosis much more frequently than pericarditis, but at autopsy it was less frequent. In 8,154 autopsies collected by Norris, valvular disease was present 293 times. Records of 60,428 patients with pulmonary tuberculosis showed that valvular disease of the heart occurred in one per cent. of the cases. Endocarditis in pulmonary tuberculosis might be due to secondary organisms or to the tubercle bacillus. Endocarditis occurring during pulmonary tuberculosis was most often a late complication, and thus passed by. He had no recollection or any definite record of endocarditis developing in a patient with pulmonary tuberculosis. Tuberculous endocarditis was very rare, and many instances reported as such could not be accepted. It was not improbable that tubercle bacilli circulating in the blood might lodge in the valves in a preexisting endocarditis. True tuberculous changes must be present in the vegetations above the elastic membrane to uphold a diagnosis of tuberculous endocarditis. Tuberculous endocarditis was so rare that it had no clinical significance, and had seldom been diagnosticated ante mortem. Thrombi in the right ventricle were rarely diagnosticated ante mortem and rarely occurred in acute cases, but usually were found late in chronic cases. They were due to changes in the endothelium, to stasts, and to changes occurring in the blood. Warthin had found thrombi in ten per

cent, of his tuberculous patients. A sudden onset of dyspnœa with crises of suffocation and a tumultuous heart's action were suggestive of this condition. Syncope or pulmonary apoplexy might occur. In more than three thousand patients who had been more or less closely followed for a number of years the writer had yet to see an instance where undoubted valvular disease developed in a patient with pulmonary tuberculosis, unless he was in a far advanced stage of the disease. A smaller proportion of patients with cardiac disease presented signs of pulmonary tuberculosis than was found in the general population. Meisenberg concluded that, given either endocarditis or pulmonary tuberculosis, the other was less frequent than occurring by itself. Otto believed that cardiac disease was more frequently associated with pulmonary tuberculosis in women than in men, but four cases out of six which the writer had had were in men. The left side of the heart was usually affected. Disease of the mitral valve was much more frequent than that of the aortic, and both were more often affected singly than together. Pure mitral insufficiency was the most frequent lesion associated with pulmonary tuberculosis, but it did not apparently predispose to pulmonary tuberculosis. The age incidence of this lesion and that of pulmonary tuberculosis coincided. In thirty-six instances of "organic murmurs" at the Phipps Institute pure mitral insufficiency occurred twenty-four times and was present in connection with other murmurs seven times. In seventy-seven instances of valvular disease in connection with pulmonary tuberculosis the writer had found pure mitral insufficiency forty-four In four other cases it was associated with other lesions. It seemed, if well compensated, to exert little influence upon the course or the symptoms of pulmonary tuberculosis. Mitral stenosis was far less frequent than insufficiency, and pulmonary tuberculosis was far less frequently associated with it than with other forms of heart disease. A number of theories had been put forth to account for this. Patients with mitral stenosis often did remarkably well. Aortic insufficiency was much rarer than many older authorities had stated. It occurred, according to Meisenberg, in 5.4 per cent., according to Norris, in 3.6 per cent., of all patients with cardiac lesions in pulmonary tuberculosis. Neither inhibiting nor predisposing influences had been attributed to it. De Renzi and others believed that this type of valvular heart disease was the most frequent in pulmonary tuberculosis. Aortic stenosis was, as would be supposed, less frequent than insufficiency, judging from both the clinical and autopsy records. Meisenberg saw it twice in 4,649 cases of pulmonary tuberculosis, and Ruck once in 3,000. The writer had seen no instance of it. Pulmonary stenosis was rare, occurring, according to Norris, in 0.12 per cent. of patients with pulmonary tuberculosis, and in four per cent. of patients with pulmonary tuberculosis and cardiac disease. Pulmonary stenosis predisposed to pulmonary tuberculosis. Pulmonary stenosis was always the primary disease, mitral insufficiency and aortic insufficiency usually the secondary. Pulmonary tuberculosis occurred more frequently with pulmonary stenosis than with any other form of cardiac disease. Mitral insufficiency was associated with pulmonary tuberculosis more often than any other form of valvular disease. Aortic

stenosis was very rarely associated with pulmonary tuberculosis, and pulmonary stenosis was infrequent in pulmonary tuberculosis. Involvement of several valves simultaneously was rare in these cases. Heart disease might render the diagnosis of tuberculosis difficult and in many instances impossible.

The treatment of the various forms of valvular heart disease occurring in connection with pulmonary tuberculosis differed in no way from that employed in ordinary cardiac disease. Arsenic, strychnine, an ice bag over the præcordium, carbonic acid baths, and rest were of value. Nitroglycerin might give relief. Excitement, alcohol, and tobacco should be avoided.

The Cerebral Complications of Ulcerative Endocarditis.—Dr. Thomas B. Futcher, of Baltimore, reported two cases of cerebral embolism complicating acute ulcerative endocarditis. In the first case there was an embolic or thrombotic obstruction of the posterior inferior cerebellar artery. As a result of the obstruction of this vessel the foci of softening were always situated in the dorsal and lateral aspect of the medulla, and these structures were more or less involved, viz., the lateral aspect of the reticular formation, the descending root of the fifth nerve and its nucleus, Gowers's ventrolateral ascending tract, the direct cerebellar tract, and the inferior cerebellar peduncle and the fibres going to it. In the second case there was blocking of the middle cerebral artery with hemiplegia of the opposite side. The heart and brain from this patient were shown.

Dr. Futcher then presented an analysis of the cases of cerebral embolism in ulcerative endocarditis that had occurred in the medical wards of Johns Hopkins Hospital since its opening, on May 15, 1889, nearly nineteen years ago. Up to March 1, 1908, there had been twenty-two cases of cerebral embolism complicating acute endocarditis. the cases there were marked cardiac features indicative of an acute endocarditis, with definite evidences of valvular lesions on physical examination. There was hemiplegia in all but one case; in this there was monoplegia of the arm. During these nineteen years there were 22,300 medical admissions to the wards, and during this period there were forty-eight cases diagnosticated as ulcerative or malignant endocarditis. From this it would appear that cerebral embolism occurred in 45.8 per cent. of the cases. In addition to the forty-eight cases of ulcerative endocarditis, there were 122 cases diagnosticated as acute endocarditis, making a total of 170 cases with an acute endocardial process. In other words, out of 170 cases of acute endocarditis, cerebral embolism occurred in twenty-two instances, or in 12.9 per cent. There were ten males and twelve females. The largest number of cases, seven, occurred in the fifth decade. The cases were chiefly in the young adults, thirteen occurring before the fortieth year, before arterial changes would be likely to occur. The predominating number of cases showed an affection of the mitral valve. Clinical signs of mitral stenosis and insufficiency occurred in nineteen of the cases. In three there was also aortic insufficiency. The hemiplegia was left sided in ten cases only, a most interesting finding. A. Ernest Jones found that in thirteen autopsies in cases of cerebral embolism in the University College Hospital, London, eight were on the left side and five on the right. Out

of a total of 558 cases he had collected from the literature, 236 were right sided, and 322, or sixty per cent., were left sided. The duration of life after the initial embolism in the fatal cases varied between two days and ten months. In their wards there had been 220 cases of hemiplegia, and in twenty-one of these the lesion was due to cerebral embolism. This would leave 198 cases in which the hemiplegia was due to apoplexy, cerebral thrombosis, tumor, or meningitis.

The Clinical Features of Myocardial Disease. -Dr. Alfred Stengel, of Philadelphia, presented this communication. All must admit, he said, that many cases of myocardial disease came to them as autopsical surprises. In considering the clinical aspects of myocardial disease he discussed it from two points of view, that of the heart itself, and that of the individual pathological lesion. Weakening of the heart, failure of heart power, chronic insufficiency of the heart, or hyposystolism showed itself by symptoms referable to the heart itself, but they were so often vague as to lead to mistakes in diagnosis. The subjective symptoms were the early expressions of this weakening of the heart muscle; the myocardium resented the ordinary strains of life. Of the visceral manifestations, hepatic symptoms were the most common, and enlargement of the liver often took place a long time before there were evidences of failing compensation. Cyanosis, ædema, dropsical conditions, etc., occurred later in cases of myocardial disease than in valvular disease. In some cases of myocardial disease there occurred only the general symptoms, nutritional and neurotic. many cases these were the earliest manifestations. Myocarditis had its origin in infectious diseases, rheumatic fever, infections of later life, strains of a severe nature occurring in early life, etc. In simple, pure endocarditis there were the same symptoms which were said to be significant of a weakened heart in general. Bradycardia occurring after typhoid fever was due to myocardial weakness. In simple myocarditis the heart might attain a large size, as described by Quain. In chronic myocarditis there might be an enlarged heart with inadequate apex impulse. Again, there was a type of cases in which the heart was enlarged, but with a strong impulse; in this the heart muscle fibres were in a relaxed condition and gave a "slapping impulse." There was much slack to be taken up. In pure chronic myocarditis one found a prolonged vibrating first sound, which was easily transformed into "murmurish." There was another group of cases associated with sclerosis, with angina, and with paroxysms of asthma, not occurring spontaneously. The effect of exercise on the heart in developing an attack of this nature was the same as the effect of exercise of the leg muscles in developing cramps and weakness of the legs. One of the most difficult things to diagnosticate was pure degeneration of the heart, and a diagnosis of fatty degeneration was impossible except conjecturally. There was a fibrous degeneration which occurred in patients with fibroid tumors of the uterus and its annexa, and oftentimes sudden death after myomectomy resulted because of this. Enlargement of the heart was associated with syphilitic disease of the heart.

Dr. W. GILMAN THOMPSON said it was interesting to note how much displacement of the heart

could occur without any special functional disturbances. He had watched experiments made by the late Dr. H. P. Loomis at Bellevue Hospital, injecting nitrogen gas to produce an artificial pneumothorax in order to compress the lung; he had seen the heart displaced to the opposite side in the course of twenty minutes or more without producing any special disturbance or discomfort. Patients at Bellevue Hospital had been subjected as a rule to deprivation, were alcoholics or syphilitics, and there were other underlying factors which weakened their resisting powers; therefore they acquired tuberculosis more readily. Bradycardia might result from inflammation of the vagus nerve, but this was a matter for clinical debate and not of actual demonstration.

Dr. ALEXANDER LAMBERT said that, in looking over more than 125 autopsical records at Bellevue Hospital, he could not find a single instance where a normal heart was found in an alcoholic.

Dr. Henry Koplik said it was rare for a child to suffer from myocarditis pure and simple. The heart symptoms following acute infectious diseases in adults, if present in children, would be most serious. In children myocardial diseases were always very serious.

Dr. Morris Manges presented specimens of acute ulcerative endocarditis and hæmorrhage into the brain. In this case it was very natural to assume the presence of pachymeningitis with hæmorrhages. The patient was found one morning in coma. The left pupil was of the size of a pin point, while the right pupil was dilated. There was right hemiplegia with lack of tactile sense. An enormous hæmorrhage was found extending as far back as the cord and anteriorly to the chiasm. The greater hæmorrhage was in the island of Reil; this had extended through the Sylvian fissure to the median line.

Dr. L. F. BISHOP said that there were many symptoms that had been supposed to be due to myocardial disease, but in the light of recent studies they were now known to be due to peripheral disease with reflex symptoms referable to the heart.

Dr. FUTCHER said he knew of no instance of hæmorrhage occurring in ulcerative endocarditis.

Dr. Brown said that, among the 1,300 cases referred to, there were but six of valvular disease, four of mitral, and two of aortic insufficiency. Five or six patients sent to the sanatorium with a diagnosis of pulmonary tuberculosis really had cardiac disease.

Letters to the Editors.

SNAKES IN IRELAND.

Bolton Landing, Lake George, N. Y., July 26, 1008.

To the Editors

I take the liberty of quoting from the editorial on the Persistence of Error, published in yesterday's issue of your Journal, the following: "Niels Horrobow opens a chapter on the Snakes in Iceland by the phrase 'There are no snakes in Iceland.' Some careless borrower made the quotation read 'Ireland,' and nothing less than a Papal bull would now correct the popular error."

Now, I do not profess to be particularly Papal, nor am I in a position to fire bulls at anybody or

against any error. But it seems there may be some reason beyond a misquotation which explains the connection between Ireland and the "absence of snakes" in that island. Baeda Venerabilis (673-735) issued in 731 The Ecclesiastical History of the English Nation, the first printed edition of which was published in Strassburg in 1473. From its first chapter I quote literally what follows in connection with the remarks on Ireland: "No reptiles are found there, and no snake can live there; for, though often carried thither out of Britain, as soon as the ship comes near the shore, and the scent of the air reaches them, they die."

The venerable bishop adds this: "On the contrary, almost all things in the island are good against poison. In short, we have known that when some persons were bitten by serpents, the scrapings of leaves of books that were brought out of Ireland, being put into water, and given them to drink, have immediately expelled the spreading poison, and as-

suaged the swelling.

The books of the twentieth century are not famous for a similar beneficial result. Their efficacy may demonstrate itself in an inverse ratio to their numbers.

A. JACOBI.

Book Aotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

A Manual of the Diseases of Infants and Children. By JOHN RUHRÄH, M. D., Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, Baltimore. Second Edition, Thoroughly Revised. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 423. (Price, \$2,50.)

The first edition of this practical manual appeared in the latter part of 1905, and the new edition, now published, has been altered in some minor respects. Several sections have been added, among them sections on the medical inspection of school children, on the duration of the danger of contagion after infectious diseases, and on the return to school of children after exposure to contagious diseases, also a short bibliography of the current pædiatric litera-

ture of 1905 and 1906.

Dr. Ruhräh has supplied in 423 pages a very valuable handbook of the diseases of infants and children. Although he states in his preface that this little book has been prepared for the medical student, not to supplant the larger and necessary textbook, the general practitioner will be glad to possess such a handy reference book, especially as the author has added a large number of references in footnotes, which will enable the reader to look up the subjects.

Die Lehre von der Intubation Von Prof. Dr. J. von Bokay, Direktor des Stefanie Kinderspitals zu Budapest, etc. Mit 113 Abbildungen und 2 Tabellen im Text. Leipzig: F. C. W. Vogel, 1908. Pp. 250. (Price, M. 10.)

This more than ordinarily well illustrated and very complete presentation covers the entire field, not only of O'Dwyer's procedure, to which naturally most space is devoted, but the allied subjects of intubation in luetic strictures, scleroma, papilloma of

the larynx, foreign bodies as well, and also takes in intubation by the mouth and the use of the tampon cannula. The author refers again and again to the genius and patient industry of O'Dwyer, and gives full credit to the other American pædiatrists and laryngologists who have been active in this Von Bokay's work is a model of a scientific review, complete, well arranged and interesting. Every detail connected with the theory and practice of intubation is considered, even to the minutiæ of the manufacture of tubes and instruments and the various questions of pathology, such as local traumatism and consecutive pneumonia. Those who wish to inform themselves on this subject will find instruction in every line, and those who already know it all will derive most pleasure from the chapters on the history of intubation, the life and experiments of Joseph O'Dwyer, the criticisms of various procedures, and the graceful yet accurate diction which distinguishes them all.

Lehrbuch der Ohrenheilkunde. Für Studierende und Aerzte. Von Dr. Georg Boenninghaus, Priv. Doz. für Ohrenheilkunde. Ohrenarzt am St. Georgs-Krankenhaus zu Breslau. Mit 139 Textabbildungen und 1 Tafel farbiger Trommelfellbilder. Berlin: S. Karger, 1908. Pp. viii-376. (Price, M. 9.80.)

The Breslau otologist has produced a textbook of medium size, in which most attention is paid to the needs of the student, and a more than usually complete account is given of the functions of the organ of hearing, the tests of these functions, and the clinical examination of the ear. The last subject, in particular, is treated of very fully, and the chapter on otoscopy, illustrated with specially prepared pen drawings and a number of colored plates, is one of the best the reviewer has ever read. The physiology of the ear is considered from the latest standpoint of clinical and laboratory research, and includes the nonacoustic functions of the inner ear, the regulation of equilibrium and muscle tonus, and the tests of this static sense. The major operations on the ear and mastoid in acute and chronic suppuration and in the various intracranial complications are considered in a separate chapter on surgery, which is admirably concise, instructive, and complete. The illustrations are mainly diagrammatic, and the various steps of the operations, as well as the dangers, anatomical landmarks, instrumental technique, and so on, are often indicated and sharply impressed with a phrase or a word. The analysis of the symptomatology and clinical diagnosis of diseases of the inner ear, a comparatively unexplored field, shows admirable clearness in the presentation of complex and obscure details.

Medical Gynæcology. By Samuel Wyllis Bandler, M. D., Fellow of the Association of American Obstetricians and Gynæcologists; Adjunct Professor of Diseases of Women, New York Postgraduate Medical School and Hospital, etc. With Original Illustrations. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 676. (Price, \$5.)

There has been manifested by our gynæcologists of late a wholesome tendency to accord importance to "medical gynæcology," that term being understood to stand for the whole of gynæcology except the major operative work, and Dr. Bandler has given us a book on the subject in which the teaching is excellent for the most part, its faults being

almost wholly those of literary style. Due space is given to the eliciting of case histories, to methods of physical examination, and to the details of treatment. A valuable section on constipation is con-

tributed by Dr. George B. Mannheimer.

Dr. Bandler devotes nearly a hundred pages to venereal diseases as they present themselves in females, and the various manifestations of gonorrhœa, in particular, are very thoroughly handled. We would commend what he has to say on the relation of uterine displacements to symptoms and "general inelasticity" (page 534). He seems to be one of the few men who understand the real action of a pessary, and he does not evince for that device the contempt which for many years our great abdominal surgeons have expressed. We can recommend the book most heartily.

A Textbook of Physiological Chemistry. By Olaf Ham-Marsten, late Professor of Medical and Physiological Chemistry in the University of Upsala. Authorised Translation, from the Author's Enlarged and Revised Sixth German Edition, by John A. Mandel, Sc. D., Professor of Chemistry in the New York University and Bellevue Hospital Medical College. First Edition. First Thousand. New York: John Wiley & Sons, 1908.

Pp. 845.

The first American edition of this excellent and comprehensive work is based on the sixth German edition, which was carefully revised and rewritten in accordance with the great advances which have been made in physiological chemistry in the three years which have elapsed between the appearance of the fifth and sixth German editions. Probably no field of medicine has seen more numerous and important advances within a few years than have been made in physiological chemistry, and for this reason it is highly important that the physician who wishes to keep himself informed should avail himself of this treatise, which furnishes a reliable con-. spectus of the present status of this branch of medi-

Hygiene and Public Health. By Louis C. Parkes, M. D., D. P. H., University of London, Consulting Sanitary Adviser to H. M. Office Works, etc., and Henry R. Kenwoon, M. B. Edin., D. P. H. Lond., Professor of Hygiene and Public Health at University College, London, etc. Third Edition, with Illustrations. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. xi-620. (Price, §3.)

By a judicious abbreviation of certain portions of the text the authors have made it possible to introduce whatever new matter was needed to maintain the standing of this admirable manual, and the third edition is worthy of all that has been said in commendation of its predecessors.

Hypnotic Therapeutics in Theory and Practice. With Numerous Illustrations of Treatment by Suggestion. By JOHN DUNCAN QUACKENBOS, A. M., M. D., Author of Hypnotism in Mental and Moral Culture, etc. New York and London: Harper & Brothers, 1908. Pp. 336.

This book, which the author states has been prepared for popular reading, has been so well exploited in the public press that most physicians have been able to form an opinion as to its value. is at a loss to understand why a physician with the author's attainments should be willing to publish as a scientific work a volume that contains so many incorrect statements. Is it possible that the author believes he has cured dementia præcox and incipient

insanity, not to mention diabetes mellitus and other diseases, by suggestion? The book can be of no value to physicians, as it is as erroneous and misleading as a manual on Christian Science.

Miscellany.

How a Great State Is Handling the Tuberculosis Problem.-Francine states that the platform on which Mr. Stewart was elected governor of Pennsylvania pledged the administration to make war against tuberculosis. The governor immediately on his inauguration requested the commissioner of health to formulate a comprehensive scheme to carry out his promise to the people. The sum of \$1,000,000 was appropriated in two sums, as follows: One of \$600,000 under an act "to provide for the establishment and maintenance of one or more separate sanatoria, or colonies, in Pennsylvania for the free care and treatment of indigent persons suffering from tuberculosis, and making an appropriation therefor"; the other, of \$400,000 provided for out of the general appropriation act, "to enable the department of health to establish and maintain, at such places in the State as may be deemed necessary, dispensaries for the free treat-

ment of indigent persons affected with tuberculosis, for the dissemination of knowledge relating to the prevention and cure of tuberculosis, for the study of social and occupational conditions that predispose to its development, and for continuing research experiments for the establishment of possible immunity and cure of said disease for two years." Acting under this authority, the commissioner of health has proceeded along the lines indicated by the letter of the law. The legislature having by special enactment called attention to "the sanatorium located on the State forestry reservation near Mont Alto in Franklin County," the commissioner proceeded to determine on the suitability of that location for the more extensive establishment contemplated. proved to be in every way desirable, having been selected by the State forestry commissioner, Dr. Joseph T. Rothrock, as the one reservation of the State best adapted for such a purpose. When taken over by the department of health, the camp at Mont Alto had accommodation for about twenty-eight cases. Already accommodation has been provided for one hundred and forty patients and plans are under way to greatly enlarge the capacity of the sanatorium. At present only incipient cases are admitted, but to meet the very urgent need for some place where advanced cases may be sent, an infirmary has been planned at Mont Alto with a capacity of one hundred beds, having the double object of segregating these patients for the public welfare and of furnishing them with every opportunity for treatment. There will also be a hospital for cases of transient and intercurrent illness and for surgical In regard to the dispensary system, sixtyseven dispensaries have been established to date, one in every county of the State, either in the county

Hatching Snakes.-Because of the popular aversion to the serpent family, there is a surprising amount of ignorance about even the simplest of snake habits. It is doubtful if many correct answers could be given to the question whether snakes lay eggs or bear their young alive. As a matter of fact, some species are viviparous and others oviparous. Most of the poisonous snakes, as well as many of our harmless varieties, belong to the former class. In the case of the viviparous species, the eggs remain in the oviduct so long that the young are hatched therein, while in other species the eggs undergo a partial incubation in the oviduct and are hatched soon after being laid. Such snakes are sometimes classed as oviviviparous. The eggs of the common water snake (America) are laid in July or August in a soft bed of loam or decaying vegetation, or in a heap of manure. The older snakes sometimes lay as many as a dozen eggs or more, and they usually stick together so that the entire cluster can be picked up at once. Sometimes, however, if the process of laying is slow, they will be separated. The eggs are about an inch long and of a whitish yellow color. The shell is thin and flexible like parchment. The young hatch in late summer or autumn. Before hatching, they develop a sharp calcareous growth on the tip of the snout known as the egg tooth, with which the shell is slit open. Unlike hatching chicks, which are suddenly

seat or the largest and most accessible town.—The Journal of the American Medical Association.

dispossessed by the breaking of their brittle shells, the young snakes may make many incisions in the parchment envelopes and take many peeps at the outside world before venturing forth into the new environment. Shortly after hatching, the egg tooth is lost. At first the young live on insects and worms, but within a few weeks they are strong enough to attack and devour young frogs. Strangely enough, although the adults are strong swimmers, and spend much time in ponds and streams hunting the fish and frogs on which they subsist, the young are unable to swim and they will soon drown if they fall into the water. The American water snake makes an excellent pet; it is perfectly harmless, becomes very tame, and learns to know the difference between friends and strangers. Gadow tells of a pet ring snake that would eat from his hand, crawl up his coat sleeve, and coil itself contentedly on his arm.—Scientific American, July 18, 1908.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending July 22, 1908:

BAHRENBURG, L. P. H., Passed Assistant Surgeon. Directed to proceed to Point Pleasant, N. J., for the purpose of examining keepers and surfmen of the Life Saving Service, upon completion of which to rejoin his station at Ellis Island, N. Y.

BARNETT, E. E., Pharmacist. Granted leave of absence for twenty-six days from August 5, 1908.

CLARK, E. S., Acting Assistant Surgeon. Leave of absence granted for ten days, from June 11, 1908, amended to

read for six days, from June 15, 1908.

CLARK, Taliaferro, Passed Assistant Surgeon. Directed to proceed to Lebanon. Pa., for special temporary duty, upon completion of which to rejoin his station at Phil-

adelphia, Pa.

EBERT, H. G., Assistant Surgeon. Relieved from special temporary duty at San Francisco, Cal., and directed to report to the medical officer in command, San Francisco Quarantine Station, Angel Island, Cal., for duty and assignment to quarters.

McGinnis, R. H., Acting Assistant Surgeon. Granted leave of absence for fifteen days, from August 17, 1908.

Mean, F. W., Surgeon. Directed to proceed to Tuckerton and Atlantic City, N. J., for the purpose of examining keepers and surfimen of the Life Saving Service, upon completion of which to rejoin his station at Savannah, Ga.

MISKIMON, R., Pharmacist. Granted leave of absence for seven days, from July 18, 1908, under paragraph 210, Service Regulations.

MULLAN, E. H., Assistant Surgeon. Granted leave of absence for two days, from July 13, 1908, on account of

Rogers, E., Pharmacist. Granted leave of absence for three days, from July 8, 1908, under paragraph 210, Service Regulations.

Service Regulations.

SAFFORD, M. V., Acting Assistant Surgeon. Granted leave of absence for five days, from July 14, 1908, under paragraph 210, Service Regulations.

SCHERESCHEWSKY, J. W., Passed Assistant Surgeon. Directed to proceed to Ocean City, Md., and Chincoteague, Wachapreague, and Cape Charles City, Va., for the control of t the purpose of examining keepers and surfmen of the Life Saving Service, upon completion of which to rejoin his station at Baltimore, Md.

TROXLER, R. F., Pharmacist. Granted leave of absence for

two days from July 17, 1908. Wasdin, Eugene, Surgeon. Granted leave of absence for one month, from August 1, 1908.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for

BAYLY, R. C., First Lieutenant. Ordered to Fort D. A. Russell, Wyo., for duty.

DEAR, W. R., First Lieutenant. Ordered to the Army General Hospital, Washington, D. C., for duty.

HARRIS, H. S. T., Major. Granted an extension of ten days to leave of absence.

JUNNSON, R. W., Major. Left Havana, Cuba, on leave of absence for one month in the United States.

KING, EDGAR, First Lieutenant. Relieved from further duty in the Philippines Division, and assigned to duty in the Army Transport Service, with station at San Fran-

cisco, Cal.

MASON, C. F., Major. Detailed to represent the Medical Department of the United States Army at the meeting of the American Public Health Association, Win-

nipeg, Manitoba, Canada, August 25 to 28, 1908. Woodbury, F. T., Captain. Ordered, at the expiration of his present leave of absence, to Fort Assinniboine,

The following named first lieutenants, Medical Reserve Corps, recently appointed from contract surgeons, United G. F. Adair, F. M. Barney, L. P. Bell, I. W. Brewer, D. P.

Card, A. M. Chase, C. L. Chase, F. J. Conzelmann, P. G. Drake, L. R. Dunbar, W. J. Enders, H. L. Freeland, L. C. Garcia, W. R. S. George, L. K. Graves, F. C. Griffis, W. C. Griswold, F. A. Halliday, D. W. Harmon, H. I. Harris, J. W. Hart, W. L. Hart, H. E. Hasseltine, O. F. Henning, A. R. Jarrett, C. W. Johnson, J. S. Kennedy, J. W. Love, F. M. McCallum, C. E. MacDonald, J. C. Magee, M. F. Marvin, A. L. Miller, S. F. O'Day, L. B. Peck, Jos. Pinquard, James Reagles, E. E. Roberts, J. L. Sanford, E. F. Slater, C. H. Stearns, J. K. Stockard, Frank Suggs, E. S. THE TONSIL FROM AN EVOLUTIONARY POINT OF VIEW.

> By Jonathan Wright, M. D., New York.

As an introduction to what I have to say, I may refer to a recent work of Brieger and Görke,' who regard at least the pharyngeal tonsil as an organ which protects childhood. They seem to find sufficient evidence to warrant them in the belief that in its hypertrophied condition it is a more efficient protection against the entrance of the unknown germs of the diseases of childhood than when it retains its normal dimensions.

Largely hypothetical as are the ideas as to the functions of the tonsils, the literature in regard to their physiological properties is of considerable extent, but into it I do not propose to go further than to remark that the view that they are only pathological entities, and therefore have no function, was founded upon opinions derived from clinical experience alone, without the benefit which accrues from a wider acquaintance with special pathology and general biological principles.

Gradually in the attention I have given the subject, extending in one form or another over many years, examining it from various points of view, expressed in several papers published in the New York Medical Journal and elsewhere, I have come to a fairly definite opinion, at least as to one of the functions of the tonsil. Whether this agrees entirely with the views of the German writers referred to before I do not know, as I have not read their pa-

pers with sufficient care to note.

In dealing with the subject of the tonsils from another point of view, I do so chiefly in the hope of bringing collateral evidence to bear from a new side, and thus by a chain of circumstantial inferences I hope to add something to what I have already presented, which may help ultimately to establish what the function of the tonsil really is.

In the first place, there is such a thing as a tonsil, quite aside from that object of revenue which the clinician contemplates in his office with feelings of satisfaction other than scientific. It is a definite organ, and in the human race it is the most highly developed of all the lymph glands, having an extent and a complexity, considering the whole faucial and laryngeal ring, entirely in excess of any other local aggregate of lymphoid tissue, except the spleen. It

is always and persistently found at the junction of the two great avenues whereby all that man assimilates is introduced to the chief organs of vital metabolism. This position at the gateway of nourishment and disease loses none of its evolutionary significance from our knowledge that like structures are found elsewhere along the food and air tubes. On the contrary, the coincidence of its position and of its extra development should of itself have due weight in the view, from an evolutionary standpoint at least, that it subserves some purpose.

It is at the beginning not only of the hollow tubes of respiration and nutrition, but it is the first of the internal nodal filters, which lie across the bypath from the surface to the vena cava, traversed by the agents of infection. If its normal state is one of comparatively little obstruction to the passage of food and air, such a condition varies between wide limits of volume, and it is impossible to draw any line between the minute structure of the normal and

that of the abnormal in size.

The enlargement becomes pathogenic, or, less accurately, pathological, only when it injures the system more by its presence than it assists it in whatever physiological acts of assimilation or defense it may have to perform. All organs exhibit this functional balance between injury and assistance of the organism. It is a symbiosis arranged by evolution.

It has been plainly demonstrated in the observations of Jennings upon the lower organisms,2 which are of the most careful and objective kind, "that when two agents, influencing an organism in opposite ways, act simultaneously, the effect of one must give way to that of the other, or the two must combine to produce a resultant. It is impossible that each should produce its characteristic effect. In such a light must be viewed the evolution of the

Many large tonsils exist from childhood to old age without in the least being either a source of danger or even of inconvenience. That question need not be discussed, but whether they are ever of great advantage in their hypertrophied state is quite another question and is one of the points here involved. Now, if there is one thing medicine has to learn from biology it is that many of the things the medicine man calls pathological are, in biological terms, variations. Their existence, even when originating in temporary disturbances of the organism (inflammation?) may not subsequently be a menace to health. They are thus not infrequently responses to environmental stimulation. If their presence in this state has any survival value for the organism,

Archie fur Larungologie, xix, No. 2.

subsequently through the action of natural selection the greater tendency to their hyperplasia, a greater tendency to give that sort of answer to an inimical agent, appears as a radical characteristic. There is a survival then of that strain in the race which has thus been able to carve its salvation out of a "pathological" entity.

It is not here in any way a question of the creation of a new organ. It is the hyperplasia of one already existent. Burbank has insisted that in the plant world new varieties are thus constantly arising out of the abnormal, out of the hypertrophy and perfection of already existent organs. If it is in its unobtrusive state a useful organ, does its efficiency increase with its size? If this is so, is its increase an individual response only, is it ontogenetic; or has it become, at least in its tendency to hypertrophy, a racial or a phylogenetic phenomenon? These are the affinities the subject of tonsillar hypertrophy has to the question of biology most voluminously and vivaciously discussed in current scientific literature.

Before entering upon its evolutionary aspect, a word must be said of its pathology. Tuberculous tonsils are not as a rule the largest of tonsils. On the contrary, they are as a rule the most submerged of tonsils. Dr. Hurd, in my clinic, has been able to predict, by a clinical study of the cases, the positive result of a microscopical examination in over half the tonsils he has sent to the laboratory. Upon this conscious or unconscious selection, this clinical suspicion, I believe depends the current statement of the comparatively high percentage (five per cent. to ten per cent.) of the tuberculous tonsils in the total number. Years before the question arose, I had sectioned and examined microscopically tonsils and adenoids from more than a hundred and twentyfive patients, and had preserved the sections. This had been done for various other purposes of study. Going back over these slides when the question of percentage was raised, now some years ago, I could not find an evidence of tubercle in a single slide. However opinions may differ as to the real percentage of the occurrence of tubercle in tonsils, it does occur, and in a large clinic tubercle in the tonsil may soon be found among those having large cervical glands, frail children for the most part, and small tonsils. On the contrary, the large tonsils of healthy children are globular and projecting, or, to put it as I have heard a clinician put it, large tonsils occur more frequently in robust than in weakly children. Of course, they may and frequently do reach such a size,—they occasionally contain such stinking pits as, after a time, to injure the patient's health. From their size they may really cut off the proper air supply; the irritation of their presence in the fauces may excite constant hyperæmia and paræsthesia, etc., etc., but all these classical symptoms by constant iteration have been much exaggerated, and, notwithstanding much platform oratory, there are a large number of children, especially in the country, who are never inconvenienced in the slightest by moderately projecting discrete faucial and pharyngeal lymphoid hypertrophies.

And now we must enter upon the evolutionary and more general biological aspect of the subject, and this, it may be thought by many, will take us to a remote and perhaps a wearisome distance from a purely medical question; but I hope the introduction of these considerations will not prove altogether unprofitable.

In our large cities a habit of life has now become established for several generations, which essentially has changed the environment of the human animal in respects most likely to effect biological changes. Such changes in the habits of life have been extended widely to children living in the country as well as to those living in town. Like all so called advances of civilization, the use of the furnace has radiated from the city as a germ centre. The present fad for sleeping outside the window is a sort of sanitary reaction. Hot air is usually, but it is not necessarily, foul air. Enough has been said about the latter. Here I wish to refer to the temperature, to the steady high temperature in living apartments. During nine tenths of the twenty-four hours we are subjected to a degree of heat especially high when the outside temperature is especially low. On passing from one side of the door to the other the human animal is now subjected to an experience to which he was all but a stranger a few generations back. It is true man has warmed himself by the fire for many generations, but first one side and then the other. Now for many consecutive hours he dwells in a uniform high temperature. Many successive civilizations have arisen, even in the historical age of the world, the Hindu, the Babylonian, the Ægyptian, the Græco-Roman, the Peruvian, the Mexican, but all have depended directly on the sun for their heat; the chimney was quite an undeveloped structure in all.

Our northern civilization is the first that has dug its heat out of the earth. This performance, little emphasized in the routine histories, of man's past has added, without a doubt, the most important biologically, as it is the most important economically, of the artificial factors to the environment of man. It is true it is but a passing phase in geological time. We are already in sight of the end of it; man must get his future heat supply from falling water, or some other shifting mass of matter, or the future as the past belong to those dwelling nearer the equator; but it has endured long enough to affect the racial heredity of man.

The modern hyperborean man as he leaves his dwelling suffers in winter a drop of some 70 or 80 degrees in the temperature of the surrounding atmosphere and of the inhaled air. Millions of the human race are thus living and adapting themselves racially to conditions hitherto foreign to their environment and foreign today to the environment of barbarous races and of those living in tropical or subtropical countries. In the systems of these large numbers of the race a call is being made upon vasomotor and cellular activities, which we know from what biology is teaching us must meet with some response and with some ontogenetic or phylogenetic adaptation which will allow the organism to respond. Not only is the high equable temperature

all give here the orthodox neo-Darwinian explanation, without, planation possible. An exactly analogous explanation is usually it for the aeration of the bones of the head, resulting in the formation of the accessory masal castities. (American Journal of the Medical Sciences, May, 1992).

for many hours a new experience, but in all probability the sudden change through the wide range of the thermometric scale is still further influential in biological effect. The sensible response to this is frequent, whatever response there may be of which our sensibility fails to take note. That response is usually a congestion and often an inflammation resulting in the hypertrophy of the lymphoid tissue of

Does natural selection or ontogenetic adaptation seize upon this response as an opportunity for the evolution of an organ to protect the young child

from air or food born infection?

Beyond the sporadic experience with the sand of the desert man has only recently been subjected to the modern city dust. It is true he has been subjected, in the swinish overcrowding of former civilizations, to bacterial infection carried from his felfow man by other means than the dust. The result of this-the repeated scourging of mankind by plagues-has brought about, by means of natural selection alone, it is urged, a resistance to such infection not possessed by savage races who have had no such racial experience. Now it must be borne in mind, if we recognize in this phenomenon of racial susceptibility a lower opsonic index or a lower bacteriolytic power in the serum, we must logically find some significance in the fact noted by many observers that these races, black and red, and modern man in the tropics have a markedly lower proportion of children with large tonsils.

Here, then, we may note a coincidence which may be significant between the tendency to enlargement of the tonsils and the natural immunity of civilized man to many infectious diseases, but we will return

to another coincidence later.

In order to emphasize the importance of temperature in shaping the destiny of protoplasm we may call to mind its influence upon that of other living

Experimental biology—like all other experimental work-can only be made useful instead of misleading by the free and unfettered use of the most unsparing criticism and by the constant precaution of the most conservative scepticism in the application of the results attained and the facts demonstrated. In searching out the workings of nature, the laboratory environment of protoplasm is of subsidiary interest and is nowhere more likely to mislead than in the discussion of evolutionary topics. Yet so far as experimental biology has gone, and so far as its testimony may be of value, its most decided positive results have been obtained in showing the effect of temperature upon the physical organization of growing animals. The experiment on butterflies, as carried out by Fischer and confirmed by Morgan, showing the effect upon these insects emerging from the chrysalis state of high and low temperatures, is less open to neo-Darwinian criticism than much of the evidence adduced for the support of the belief in the transmission of acquired characteristics. From the observation of the processes of nature itself the conclusion has been drawn by a neo-Lamarckian that "the wonderful adjustment of critical temperatures to the environment of the species is not to be regarded as evidence of selection—but

it is due to the modification wrought in the protoplasm by the temperature itself. Weismann' indeed ascribes these results, which he also has obtained, to the cumulative influence of the temperature, but his most ingenious theory of germinal selection, which may be easily extended to a chemical conception by calling it molecular selection, aids him in avoiding a neo-Lamarckian conclusion.

However that may be, he seems compelled here to admit that the environment of the temperature in many instances, both in the animal and the plant world, seem to affect the germ cells as well as the somatic cells—a modification of his early views, which, it seems to me, alters his position totally in principle. If such facts have been so evident as to force the arch defender of exclusive natural selection into such a radical change of base, it is reasonable, at least, to suppose that temperature is doing something to man's physical organization. It is not alone in the color of butterflies' wings that the effect of temperature on the germ plasm has been cited. The observations, as I have just intimated, have been far wider than that. For instance, Kammerer, having observed that certain eels reproduce oviparously, i. e., by eggs, in high temperature, viviparously in low temperature, by experimentation on certain salamanders exhibiting the same tendency, he influenced that tendency for three or four generations by the cumulative effects of temperatures on preceding generations. The tendency to vary as to these conditions was present, and doubtless this may be the neo-Darwinian answer, the tendency to vary around a certain mean-but I am not here concerned with this biological war. I only want to suggest that we may be observing something of the same phenomenon in tonsillar hypertrophy, due to the artificial environment of man. Man has thus subjected himself artificially to that agent which has been the most potent of all in the production of cosmic change. For it seems certain that the change in temperature, coincident as it has been with the change in the configuration of the surface of the globe, has been scarcely less influential in the birth and shaping of protoplasm. Upon this broad principle of such universal application, we may be fairly sure, depends the quick response of protoplasm to changes of temperature. This is the price of its survival, the ability to live and reproduce in the frigid temperature of the arctic zone-like some of the mosses-and the ability to exist in the water of boiling springslike some of the bacteria. Yet through this all is retained that tendency of protoplasm to thrive best within comparatively narrow limits of temperature, which Quiton insists was inherited from its birth, and which he has formulated as "the law of original thermal constancy," intimating thereby the immensity of time which it must have taken to impress thus indelibly upon nascent protoplasm this adaptation to the temperature prevailing at its birth. The temperature of the coldest blooded fishes is but a few degrees below that of the hottest blooded birds, and if this is so for such complex and highly

adapted organisms, the survival of naked protoplasm must have been confined to an environment of a very narrow range of temperature, but for an extent of time that defies computation. This oscillation between the narrow limits of life and death at its birth, the first panting of the complex molecule we call "life," by the constant weeding process of almost infinite time has extended until now it has its supreme illustration of survival within wide limits in the range of man alone from the tropics to the pole.

Such an influence of change, applied even for only two or three generations, might result in a sensible thinning out by natural selection of the inept, or by a sensible adaptation of the germ plasm. Applied more universally and more continuously to the infant or adolescent animal, it is brought to bear on millions in a way and at a time which renders it an ideal experiment in biology.

While I have alluded to the fact that tonsils, which clinically we would call enlarged beyond the normal, may throughout adolescence exist in the throat without injury to the organism, it remains to show the affinity this observation has to the facts pointed out by Baldwin, Jennings, and others, from which they have constructed their theory of organic selection. Numerous characteristics of living things are supposed to arise from the tendency of protoplasm to vary in many ways, which have, under many conditions of environment, no survival value,° that is, they tell neither for nor against the survival of the race with sufficient force to influence individual selection. When the environment changes, such variations always become racially more numerous. At the same time, when such environmental change occurs natural selection needs a new base from which to work, and finds it broadened in this broadening of the field of variation from which to select. Change in the habits of man brought about by the forces of civilization may be supposed to increase the frequency of tonsillar enlargement, and it certainly increases the amount of bacteria laden dust. The absorption of these from the pits on the surface of tonsils where drainage and inspiration have carried them, where they have lodged from passing food, is increased, and the inner organs of defense make a larger demand on the outer organs of defense for protection. The more bacteria there are on the surface the greater number there are absorbed, unless a lining epithelial or subepithelial tissue is so evolved as to limit the number to the capabilities of the bacterolytic power of the inner organism.10 In other papers I have attempted to show that the epithelium of the tonsillar crypt, or the lymphoid tissue contiguous to it, exercises differentiation between bacteria and dust, and that during differing conditions of the system we have evidence of differing degrees of per-

meability of this tissue in its relation to the bacteria of the tonsillar crypt. Is it possible, I repeat, that natural selection or individual adaptation has not seized upon this variation for evolution?

The clue of a connection which may exist between the hypertrophy and the efficiency of the organ as a bacterial filter possibly may be found in the observation of Dr. Hurd and others that the small submerged tonsil is the tonsil of infection, and the large discrete tonsil is the tonsil of health.

But whether from the facts the inference is warranted that such hypertrophy is ever beneficial, whether it is an index of efficiency, or whether the efficiency of the organ may not be increased without such hypertrophy, are questions which for the lack of more direct testimony must depend on side lights derived from other biological facts. The regulation in the size of such an organ in the process of evolution would be governed by the same laws of symbiosis which arrange the equilibrium existing in all living things. The price of its existence at all is that it renders as much or more help to the organism, as a whole, than it does of harm. Other structures, other activities, such as I have instanced in the defensive reactions of the serum, must also be rearranged in heredity. To shut out more oxygen than is gained in any hæmatapoietic function it may have, like the spleen or the bone marrow, would mean its recession in size. The filtering index remaining the same, and there being the same index of bacteriolysis, a deepening of the pits, affording a larger lodging space for pathogenic bacteria, would result in destruction. Thus by natural selection there would be a tendency for the pits to grow shallower, for the tonsils to disappear. Whatever else is happening, it is not this. The pits are deepening, and yet man is surviving. This survival must then be due to a change in the filtering or bacteriolytic index, or both. In former papers I have tried to show it is not exclusively due to the internal agencies of immunity. Nasal catarrh, by increasing the drip from the nose into the pharynx, increases the number of germs carried into the tonsillar lacunæ. The coincidence of large tonsils, the deepening of their folds, and chronic rhinitis is a well known clinical phenomenon.

The pits of the tonsils, for as folds they exist to some extent in all human infants, may indeed be cesspools, but from the argument thus far they must inevitably be also more or less impermeable retorts. They are retorts in which the germs are either destroyed, or modified so they may live at peace with their host, or they are allowed to pass through only in such numbers as can be dealt with by internal processes without the destruction of the host.

Any one who may have had the patience to follow me thus far, in this paper and in others," will understand that the mechanism which evolution has thus affected I ascribe to the existence of that layer of electricity which exists on the surface of all colloid bodies and which we call "surface tension," and its reciprocal reactions with contiguous heterogeneous colloid and inert bodies. In the same way it

both of the first beautiful to the condition of the first beautiful to the first beautiful

disease. The tonsillar crypts do this with a distinction and a discrimination impossible for a nonliving membrane, letting the bacteria

Varies Equation of Dust from that of Bacteria in the Difference in the Behavior of Dust from that of Bacteria in the Difference in classiff view both Week, all Journal January 6, 1990. The Physical Processes of Immunity and Infection, Toldem, February, March, April, 1997.

will be understood why that process seems to be so highly developed in the region of the pharvngeal lymphoid ring. That is the spot on which first impinges the unmodified pathogenic germ from man's external environment. Excluded from the internal organism and kept on the move, by the time the pathogenic germs reach the absorbing surface of the intestines, if they have not been destroyed, much has been done to render them harmless, and they may pass through in larger numbers without causing the death of their host. As a matter of fact there is much evidence to show, and here the evidence is all but conclusive, that the intestinal epithelium sharply distinguished between nutritious prepared albumen and harmful protoplasm.

For years we have been familiar with the fact that healthy people carry about with them in their mouths pathogenic microorganisms. In the intestines the same thing has been observed for the tvphoid bacillus and the cholera vibrio, even when the bearers of them have never had, or have not had for years, the diseases they cause in others. Such persons have been shown to have in their blood serum, in the cases examined, such an abundance of the specific antibodies that the presumption was entertained that the reaction to the bacteria in the intestinal canal supplied these bodies for absorption, but it seems to me more justifiable to conclude that these bacteria are allowed to pass in such numbers through the intestinal epithelium as to keep up an autoinoculation-for this is more in accord with other facts.

From various clinical facts, to some of which I have alluded, it seems likely it is the small sunken, ragged tonsil, and not the large tonsil, which lets through the dangerous germ. Whether it is a septic or a tuberculous germ, the lymph nodes below swell up as a result of a local or systemic reaction, which seems calculated to retard the passage of the germ to the vena cava. Increase in size of the cervical lymph nodes can hardly be accepted as evidence of an increase in the filtering efficiency of their lymphoid structure without ascribing as much or more to the lymphoid structure of the tonsil and its coverings. The surgeon knows how much the absorption of cocaine is retarded on the inflamed surface. Swelling of the tonsil, then, appears to some extent as a closing of the gate in acute conditions. Chronic enlargement seems clinically a sequence, but may it not be regarded physiologically as a continuation of the reaction? Does it not seem, keeping in mind the blind sort of way protoplasm varies, that it is an awkward move to keep the gate partly closed? It is certainly awkward, for it deepens the pits and narrows the air and food way; but then, protoplasm has had no university education in physiology. No modern laryngologist has ever made her understand that really she should not act in that way.

In childhood the susceptibility of the internal structures and fluids, the resisting power exerted against bacterial disease, is at a low point. Young frogs, those caught in the spring, are known when injected to be much more susceptible of systemic infection.12 This is the universal testimony, not only in biology but in clinical experience and in general observation, for all animal life. Calmette and Guerin'

point out that it is the lymphoid structures which attempt to supply this deficiency. The younger the animals (guinea pigs, etc.) were in their experiments, the more efficient was the ganglionic filtering of the injected tubercle bacillus, allowing time apparently for a more general phagocytosis than in older animals. This means a modification of the tension on the surfaces of bacillus and leucocyte. This coincides with the argument here advanced as to the function of the tonsils in childhood. Here, at least, we may believe the experimental evidence has the support of that supplied from nature by clinical observation.

It has been noted " that certain starfishes occasionally have one of their parts infected by a parasite. Finally a process of "autotomie" is set up whereby the affected part is self amputated. This part being, however, a necessary and integral part of the organism, is subsequently regenerated. This

has a two fold interest for us.

First.—The shedding of a part after it has become useless and a menace to the organism in general, like the action of sloughing, has its analogue in the process which I have described as autoclasis of the tonsil.15 Of course, this shrinkage of the tonsil, as adolescence passes into mature life, is probably chiefly a process of phagocytosis, a devouring of the leucocytes by the macrophages, the autoclasis being an auxiliary process. This has its counterpart in the shrinkage of the thymus gland and the other appurtenances of embryonic life, and the disappearance of the tadpole's tail when its life becomes to a large extent terrestrial.

Second.—Neither the young frog nor the infant regenerate their shrunken parts, nor, as a rule, do the tonsils grow again in adolescence after being removed either automatically or by operation. In the infant, however, in the child younger than four, clinical experience teaches that in quite a proportion of cases, recurrence of the hypertrophy takes place. It is difficult to look upon this performance of the human organism in any other light than we look upon the performance of the starfish's restitution af-

ter "autotomie." They need them.

In what I have written here I do not wish to be misunderstood. I do not wish positively to assert that the enlargements of the tonsils are always a protective physiological act of the organism. Neither do I wish to deny they are frequently, or even usually in adolescence, solely a menace when diseased. I simply have endeavored to gather some evidence from the fields of pathology and of clinical observation as well as from the broader field of general biology, suggestive of a place their enlargement possibly may occupy among the phenomena of organic evolution. Nevertheless, whatever may be the conclusions as to their marked enlargement, the knowledge derived from all these sources and the experimental evidence, which I have elsewhere adduced, unite in pointing to the function of the tonsils as one of defense against infection. The tendency to enlargement seems a persistence of the process by which the function was evolved.

CONFESSIONS OF A YEOMAN PROSTATEC-

By Joseph Rilus Eastman, M. D.,

At the last meeting of the American Urological Association Dr. Granville McGowan, of Los Angeles, said of prostatectomy that "the difficulties of the operation have been so minimized, the benefits in many cases so magnified, and imperfect results so glossed over or concealed by writers of known operative skill, that many who have only a very uncertain idea of the anatomy of the urogenital organs are emboldened to commence operations which they never finish, and the necessity for which is often only problematical. So much bad work of this nature is being done that this very beneficent operation may easily fall into disrepute.'

A man about to undergo prostatectomy manifestly places his life in the hands of the surgeon who operates upon him. The author of the method employed contributes somewhat to the result, but in no such degree as the operator in the individual case. Any operator is absurd who lays the blame for his failures and disappointments upon faulty methods without assuming the lion's share of culpability for his lack of judgment and skill and his clumsiness as an executant.

As we stand marveling at the machinelike technique of Young, and Mayo, and Freyer, among other impressions which we chronicle is the one that the methods which bear the names of these men are theirs, indeed, and no one's else in the same sense. Their records pertain less to their methods

than to themselves and their genius.

Gask sews up the wound in the bladder after suprapubic prostatectomy, depending only upon a catheter drain, and Freyer leaves in a tube large enough to remind one of a steamboat funnel, laying the utmost stress upon the ample drain. Each has amazingly good results, yet each condemns the other's plan. Gask takes plenty of time and Freyer operates by the split second watch. The man is more important than his method.

How well even the unskilled realize that, with increasing experience and increasing devotion, come sounder judgment and increased precision of technique, and, therefore, better results.

This quickly explains why one surgeon has lost of twenty-six patients treated by prostatectomy more than fifteen per cent. It explains his fistulæ, perineal and urethrorectal, and protracted periods of convalescence, as it explains loss of sexual power and incontinence.

There are some events, however, which it does

not explain.

Like many others, I have found it difficult before operation to distinguish between benign and malignant enlargements of the prostate gland. Albarran and Halle, in a series of one hundred cases of supposed benign prostatic hypertrophy, found carcinoma, as has been frequently quoted, in fourteen cases. This percentage of malignant enlargements seems rather high, yet C. H. Mayo found in two hundred and ninety-one cases of prostatic over-growth twenty-six implications by carcinoma, or

almost nine per cent. Mayo had twenty-eight

There is no doubt that some men of great experience have the acumen necessary to determine quite definitely before operation the character of a prostatic enlargement, a faculty quite beyond me and many of my colleagues, and I realize that they cannot if they would share with us that fine judgment and art which comes only out of an experience remarkable both for its length and its fibre.

In my own short experience I have had a death from prostatic carcinoma, there having been in evidence only a smooth, round projection into the bladder, involving the posterior median commissure, and I have advised a man with a bossed and nodulated prostate and cachexia to be operated upon for carcinoma, and he recovered completely without

operation.

The most accomplished prostatectomist in the world makes the statement that the general recognition of the increasing frequency of carcinoma of the prostate renders it imperative that early diagnosis and radical operations be made. During the past four years he says there has appeared in his own practice one case of cancer to every four cases

of hypertrophy of the prostate.

Hawley (Annals of Surgery, June, 1904) mentions Engelbach, Burkhardt, Craison, Harrison, Green, Brooks, Belfield, von Frisch, and many other writers who have spoken more or less recently of the unappreciated relative frequency of carcinoma of the prostate. Writers, old and new, have called attention to the rather frequent association of hypertrophy with cancer, and although Powers (Annals of Surgery, January, 1908) could find record of but twenty-nine cases of sarcoma of the prostate, and whereas, no doubt, sarcoma is rare in the prostate, nevertheless malignant disease, generally speaking, is common. Labadie and Harrison have remarked, as has Hawley in support of them, that carcinoma of the prostate is far more common than we have been led to think.

The surgeon who does not systematically submit his extirpated prostates to a competent pathologist for microscopic examination cannot know what he has removed. It is now well known that many so called hypertrophied prostates, exhibited as such in collections, have been found to be cancerous. The lymph glands may not be involved and there may

be no distinguishing symptom.

Dr. Mayo, in his whole list of prostatectomies, lost twenty-eight. All but two of the fatal cases were cancerous, from which it will be seen that Dr. Mayo's record is best of all, unless, perhaps, others like himself have included all cases as they met them, cancerous or not, as prostatectomies. can learn nothing from statistics as to the comparative value of methods unless all the facts are clear. The comparatively inexperienced are misled by ambiguous reports.

A series of one hundred cases of prostatic enlargement without a single case of carcinoma would represent a remarkable series, indeed. Therefore, not to expect some failures in such a series is folly. No one will wish to refute this statement. Yet there are those who inadvertently leave the impresragase of 19001)

sion that, with the best present knowledge and skill, a series of one hundred successive successful prostatectomies may be attained. Is it not fair to say that the most trusted authorities often carelessly fail to make clear that their lists of successful prostatectomies do not concern carcinoma, for the patients with carcinoma die more or less promptly, and it is fair to assume that success means permanent relief?

Should not one giving results in the form of statistics make clear whether the term prostatectomy is taken to mean the removal of only benign so called hypertrophied prostates or the removal of all prostates, ad seriatim, for any cause, according to

the interpretation of Charles Mayo?

Are we not comparing incomparable things? Should there not also be a clearer understanding as to what constitutes death from prostatectomy in cases complicated with serious lesions beyond the

prostate?

Dr. Bryan, of Richmond, makes, I think, a representative presentation when he says that, "Were the prostate the only cause of the patient's condition, it could be speedily remedied, but those conditions which have been going hand in hand with the enlarging prostate have also been undergoing a pathological metamorphosis. Surgery cannot rectify in as many minutes conditions which have taken years to obtain. The bladder wall, the ureters, the pelvis and kidney substance, the heart, the arteries, the general anæmia, depletion, and urosepsis, incident to damming back of waste products destined for excretion, and not for systemic absorption, are also to be reckoned with and cautiously weighed. . . . In the normal man, perineal prostatectomy is nothing more than a deeper dissection of an external urethrotomy and should be attended with no more risk; but a prostatectomy is never performed in a healthy subject. It is essentially a disease of advanced life, senile changes, contracted kidney, and atheromatous arteries-pathological states which call for the physician's advice aside from any operative procedure. . . . The anæsthetic, the shock (primary and delayed), hæmorrhage, congestion of the kidney, uræmia, pulmonary œdema, embolism, lowered index of repair, and other less frequent complications and sequelæ, are sufficient to pronounce the operation of severe character, attended with more than ordinary risk, but, of course, with brilliant results in selected cases.

There is little doubt that renal infection is best treated by good bladder drainage, but should we, whose experience in prostatectomy scarcely surpasses the score, subscribe to the unqualified statement that such drainage is best obtained by removal of the prostate through the perinæum? Mechanically, this gives the best drainage, but is it always wise to take the risk attending prostatectomy in order to provide drainage which can be had with

so much less hazard?

One excellent authority states that he rarely finds preliminary drainage necessary, but elsewhere remarks that prostatectomy is undertaken in cases of renal infection and other complications if the patient has not improved on preliminary treatment, as catheter drainage. I have seen a man vomit himself to death after prostatectomy who, I believe,

might have been saved by efficient preliminary drainage.

The surgeon who does not select his cases, excluding some from operation, must, in the very nature of the elementary propositions of pathology, some time lose one from uræmia.

The enlarged prostate and inflamed bladder militate against exact diagnosis of the kidney compli-

cation.

The intense suffering attending a violent cystitis and renal infection will determine the patient's choice in favor of operation despite the great risk in nearly every case, and the surgeon who would refuse to operate in such a case is worse than a manipulator of statistics, and yet, in view of established principles of pathology and prognosis pertinent in such cases, I cannot understand how death is averted by others. In my relatively short career, two patients have died from uræmia and after operations in which I thought I had in a reasonable measure mastered the principles of technique of those who avert death from this cause.

The moral stands forth that the only efficient means of preventing cystitis and renal infection as a complication is so to establish prostatectomy in the esteem of physicians and laity that it will be accepted readily as the only useful method of treatment when catheter life would otherwise begin. This statement, made in 1904 by Moore, of Minneapolis, true then and truer now, in view of perfection of technique, should be the motto and maxim of every

prostatectomist.

I am unable to minimize the dangers of prostatectomy and its seriousness to the degree of forgetting the large element of safety provided by preliminary cystostomy, the prostatectomy in two stages recom-

mended by Chetwood and Summers.

The published reports of the most trusted authorities say precious little of draining first. Many of us are called into the country at night to "a Prostatiker" with acute retention, whose prostatic urethra has almost certainly been brutely traumatized and perhaps infected by efforts at catheterization. Such cases must be first drained. Freyer often drains first. Young's last report is silent upon this point.

It is unreasonable to expect preservation of the sexual or procreative power after Freyer's operation. Freyer has quite given up this contention. Being asked by the writer whether he professed to preserve normal sexual power after his operation, Freyer made the significant reply: "Not any more." It will be remembered that Freyer states that he divides the urethra behind the opening of the ejaculatory ducts. The verumontanum and sinus pocularis are visible, however, in his specimens at the Royal Museum.

Eldred Corner, of St. Thomas's Hospital, who, like everybody else in England, makes practically the same operation that Freyer calls his own, and who lost only one patient in his first twenty-five cases, sees small chance of saving the ducts in the complete English suprapubic operation. Freyer does not expect it now. He now defines success as meaning that the patient regains the power of retaining and passing the urine without the aid of a

Young's operation done by himself offers the

best chance of preservation of the reproductive ap-

I imagine, however, that others of small experience like myself have often in performing Young's operation so traumatized the pubic vessels and nerves and muscles as to preclude the reappearance of sexual strength after the perineal prostatectomy.

Mayo's operation, which, as done by Mayo himself, is attended by the minimum of trauma to the perineal vessels, nerves, and muscles, cannot be done, it seems to me, by an ordinary man without incidental tearing of the ejaculatory ducts.

Perhaps when we have learned to do a Young's operation quite properly we can eliminate the danger to the ducts, as well as to the vessels, nerves,

and muscles.

To one who has had fistulæ galore, the suprapubic operation of Fuller and Freyer appeals as it cannot to those who have been more fortunate or more skillful. Mr. Rawlings, of Guy's Hospital, says fistulæ are unknown in England. Freyer says

he never had one.

If Young has been ingenious enough to avoid fistulæ by precisely bringing together the edges of the levatores ani and prompt removal of the gauze and drain on the second day, still it can hardly be denied that the puncturing of the prostatic sheath or vesicorectal fascia will, in the experience of most men, be accompanied by some likelihood of fistulæ formation. This danger must, in the nature of things, be slighter when, as in the suprapubic operation, the gland is lifted off the fascia instead of being pulled down through it.

McClaren and Mayo and all those who reach up through the prostatic urethra and enucleate the prostate through the mucous surface, can theoretically and practically excochleate the gland with very slight or no injury to the vesicorectal fascia. Perhaps this factor accounts in some measure for the rarity of fistulæ after the intraurethral attack.

Concerning dribbling of urine after prostatectomy, Fuller, quoted by Porter, says that in four hundred cases he has had but one instance of permanent dribbling, and in that case the dribbling oc-

curred only on exertion.

So skillful and experienced a man as Fuller can, doubtless, turn out the prostate with no injury to the sphincter muscles or the nerves controlling them, but I believe that when the truth is known of the results of the average genitourinary surgeon, and I judge largely by my own disagreeable experiences, it will appear that dribbling after prostatectomy, varying from slight transitory dribbling to complete incompetence, presents itself in a considerable percentage of cases. After all of my first ten prostatectomies the patients dribbled somewhat.

I have observed prolonged dribbling several times after forcible dilatation of the prostatic urethra for stricture, and certainly it may be expected to follow

prostatectomy occasionally.

Leakage due to the leaving of lobules at the urethral orifice and to injury of the sphincters has appeared repeatedly in my commonplace record. I trust that by approaching the prostate back of the bulb and triangular ligament I may do less damage in the future. However, like McGowan, the bad realts which I have seen have not always been attributable to my own inexperience. At least a score of men wearing urinals after prostatectomy done by the most distinguished and most skillful of operators have drifted back to me. If it befits the experience of one man to say that enuresis after prostatectomy is a bugaboo and myth, it cannot be applied to the experience of many. The man with the urinal stalks about, a very present admonition for more careful treatment of the sphincters, and more precise and thorough removal of nodules about them.

ANTW YORK MIDICAL JOURNAL

This is a matter to which we may with profit address our interested endeavor, for out of my own unfortunate experience I know that a careful but relatively inexperienced operator may easily tear through that portion of the external sphincter just below the urethra and in front of the third lobe, an accident very likely to be followed by incon-

With proper care on the part of operator and assistants, it should be possible to avoid injury to the rectum, but notwithstanding excellent authority to the contrary, I submit that in the hands of the ordinary man this accident cannot be excluded. It is my observation that injury to the rectum occurs not usually, as has been stated, because a retracter blade has been pushed through it, but rather because of too great lateral traction by too powerful pulling on the retracters, as the result of which the rectum is split. As Moore has said, none but an experienced and trustworthy assistant should be allowed to hold the retracters. We who are obliged to operate in country homes and are compelled by professional amenities and absurd interpretations of ethics to allow the family physician to assist, have usually the greatest sense of security when such an assistant is placed at the distal end of a long handled retracter, but in prostatectomy he is by no means innocuous in this relation, as I have found to my sorrow. Such an accident will almost never occur in a modern operating room, with a well trained operating corps, but I would take my oath that they do occur in farmhouses in Indiana.

The tearing of the rectum is perhaps not a disastrous event, but it is always an annoying complication, and often a serious one.

Several years ago Watson, of Boston, speaking of prostatectomy, said that we are justified in saying that patients should be given the benefit of it at a much earlier stage of the malady than it has been customary to apply it, and that where it is applied by those skilled in its performance, as soon as the hypertrophy can be clearly detected by examination, and if at the same time it is already giving rise to well marked symptoms, and the patient's condition is not unfavorable to the performance of an operation of this magnitude, the mortality of the operations, were they applied at that time, will be a trifling one, and their risks not nearly so great as those entailed by the use of the catheter, assuming the latter to have been employed instead and under the same conditions.

Operative treatment has now reached the status at which we are justified in saying that all cases of prostatic hypertrophy should be treated by prostatectomy, partial or complete, as soon as it has begun to preduce annoving symptoms. It is important

that we should not wait until the last word has been said upon technique before we unanimously and with emphasis plead for early operation in this as in other painful and fatal maladies. When the profession generally appreciates the importance of early prostatectomy, before serious complications have developed, then the prostatectomist of average skill, the yeoman, may be able to approach more nearly to the standards of the masters.

REAL CONSERVATISM IN THE TREATMENT OF THE PROSTATIC.*

By G. Morgan Muren, M. D., Brooklyn, N. Y.,

Professor of Genitourinary Surgery and Venereal Diseases, Brooklyn Postgraduate Medical School; Genitourinary Surgeon, Williamsburg Hospital.

In the many papers upon senile hypertrophy of the prostate gland and the train of symptoms due to this common condition that have appeared during the past few years, two points must be apparent to the careful student of this very voluminous literature: First: The writer's remarkably good results. particularly as regards mortality. Second: The cases reported are almost always "selected."

In these reports much attention is given to technique, and the credit for the good results attained is usually given to the rapid and easy method of operation as described by the authors. Most men have a decided preference for one of the two routes of removal and seem ready to believe that poor results are frequently obtained by other surgeons because the opposite route to their own has been selected.

As I have stated in a previous paper, I am positively in favor of the removal of the gland whenever

the patient's condition justifies the risk.

The surgeon who advises an elderly man, about to begin catheter life, that this method of relief may be continued and operation postponed until a more positive obstruction is present, is a poor counselor.

The man advanced in years, who finds increasing difficulty in emptying his bladder, due to an enlarged prostate, and is finally unable to relieve himself except by catheter, should be operated upon at once and not allowed to continue catheter life at all. This opinion, I believe, is shared by most genitourinary surgeons. The cases in which I believe operation should be postponed, for a while at least, will be considered later.

Regarding the two points noted in most prostatic literature, "low mortality rate," and "selected cases," I confess great wonder at the results obtained by some men and grave doubt of the truthfulness of other writers, when I consider the cases that I have personally noted and the poor results so often obtained

We must of course "select" suitable cases for opration, but too little consideration has been given in he literature and in practice to those unfortunates who cannot be counted in this elect class.

It has been my privilege to observe the work of everal other men and to follow their cases after operation, through convalescence or until the death

Personally I have operated upon nearly one hundred patients, using the various methods of operation and the several tractors, forceps, etc., and have treated and observed in consultation a much larger number. These facts are mentioned as some justification for my ideas upon the treatment of these cases, as I know they are somewhat opposed to those held by many competent genitourinary surgeons, whose usual practice is the removal of the prostate. Admitting, then, that the fortunate individual who may be classed as a "selected" case be operated upon early in catheter life, or before it has been really commenced, what shall we do for the "unselected," who suffers severely and clamors with his family for some relief?

In a number of these cases where great infirmity, crippled kidneys and heart, contraindicate the immediate removal of the gland, the "two stage" operation may be well borne. By this is meant the preliminary drainage of the bladder, and later, when the patient has sufficiently improved, the complete

removal of the gland.

This preliminary drainage done with local anæsthesia affords almost immediate relief in many cases, from the urgent symptoms. Several days or a week later, the urine improving and the patient having had a number of quiet nights' rest with freedom from the constant calls to urinate, comes to the radical operation in greatly improved condition to stand the severe shock that is suffered by practically all old men who undergo these operations.

Until recently it has been my practice to drain these cases by the perineal route and later to remove the gland in the same way. Recently I have been draining suprapubically, as it seems to be a more rapid method, the abdominal tube disturbs the patient less, and if later there is not sufficient improvement to warrant prostatectomy the suprapubic fis-

tula may be made permanent.

In the literature of this subject we occasionally come across a paper on the "nonoperative treatment of the prostate." Rarely are these articles by men of any large experience in bladder and prostatic surgery, and most of us, I feel sure, have come to believe that there can be little or no change produced in the senile gland, and that the radical operation is the only means we have of removing the obstruction to the outflow of urine from the bladder. There can be no disagreement with this opinion except in one class of cases; in this class, in addition to the chronic enlargement and distortion, which we cannot hope to overcome by any internal medication or other treatment, there is, I am sure, an acute congestion and inflammation with an additional enlargement of the gland, which is the immediate cause of the retention for which these patients seek relief.

In these cases the old men have suffered practically no urinary disturbance until the acute condition produces total retention. Shall we operate upon these patients at once? I am sure that we should not. Two recent cases of my own will illustrate

that operation is not always indicated.

CASE I.—The first patient was seen last fall with Dr. A. E. Gilmartin, of Brooklyn. The patient was seventy-three years

^{*}Read before the American Urological Association, No. Yes, safety, May, 1918.

old and had noticed slight bladder irritation for about a year, rising twice each night to urinate. Suddenly, from no apparent cause, he had complete retention, relieved for several days by catheter, followed by a period of great irritability of the bladder, during which I saw him. His residual urine was about 40 c.c., and his bladder capacity 200 c.c. His prostate was much enlarged and quite hard. His general health was and always had been excellent. I advised the two stage prostatectomy by the perineal route, and this being refused by the patient and his family, bladder washings and the use of urotropin were continued by Dr. Gilmartin. To my surprise, in the course of several weeks Dr. Gilmartin informed me that the patient was able to void urine, had almost no residual, and was up and

Case II.—The second case was referred to my service at the Williamsburg Hospital during the past winter for operation by Dr. Gilmartin. The patient was sixty-nine years old, a vigorous young-old man, had suffered from total retention for several days, and had been rather roughly handled before consulting Dr. Gilmartin. He was willing to have the prostate removed, but stated that he had a large family and was anxious to return to work. On this account he was kept under observation for a week, at the end of which time the gland somewhat decreased in size and he again voided urine. He soon left the hospital and has not since reported, as he was instructed to do, but Dr. Gilmartin informs me that he is in good condition.

If these two cases had been subjected to the radical operation who can say what the mortality would have been? Now they are in no worse condition than before the acute retention. Later, if their symptoms indicate it, more radical treatment can be considered. At least the patients are alive and at the time of writing this paper are both in good condition.

Unselected Cases.—There are several classes of cases in which there is every reason not to attack the prostate, and yet these patients are subjected to the radical operation with little or no improvement in their condition if they live, and frequently their deaths are greatly hastened. An old, broken down prostatic who has had little or no treatment before admission to the hospital may, after a week or ten days' careful attention, show such marked improvement as to be fit for operation. There is a large number, however, so fragile and worn out that any attempt to remove the gland must prove fatal.

In these cases I believe permanent suprapuble drainage is the treatment indicated. It is a curious fact that little mention of this method of relieving the prostatic can be found in the literature. And the only textbook author that gives it careful consideration is Deaver (1), who has this to say of it: "Cystotomy for enlargement of the prostate is a very valuable operation, not lightly to be discarded; it is a step between catheterism and prostatectomy."

The very occasional resort to this method is due, no doubt, in a large measure, to the difficulty in controlling the bladder and the more or less constant wetting of the clothes, in spite of the several obturators and permanent drains that have been devised.

Preference is given to the suprapuble method of drainage as there is less subsequent dribbling than be the permeal, be disconfert from the tube or obturator, no added irritation to the inflamed vesical neal and the mercer of the bladder can be explored at the time of operation.

Local and the date all that is needed, and in urgert face I have opened the bladder without moving the patient from his bed.

The encrateer need no description before this

society except to note that the skin incision should be rather high, the one in the bladder low. The large drainage tube is left in the bladder three or four days, and after its removal the wound "glazes" over and heals rapidly, the opening rarely showing any tendency to close if the obstruction below is complete.

When the wound is healed some form of obturator or permanent drain is usually needed. McGuire's obturator I have tried, but it produced considerable discomfort. Senn's sigmoid tube I have never used.

My own apparatus, by no means perfect, is much like Stevenson's. I have found it necessary to have one made for each case, as the fistulæ are rarely alike in any two patients.

Cases are occasionally met with where no obturator or tube is required, of which the following is an example:

CASE III.—H. E. W., farmer, aged fifty-nine years. I saw him through the courtesy of Dr. W. H. Ross, of Brentwood, Long Island, in February, 1906. For the two previous weeks he had almost complete retention. His lower extremities, hands, and penis were markedly edematous. His heart irritable and irregular, though no organic lesion could be detected.

Two efforts at general anæsthesia, with the idea of re moving the prostate, had to be discontinued, as the patient nearly died from the effects of the ether. Permanent suprapubic drainage was done, and after the wound had healed the patient could sit in a chair for two hours and then void the urine comfortably by lying on his side. At night he also had very good control.

Another case, seen through the courtesy of Dr. F. J. J. Wood, of Brooklyn, in October, 1907, illustrates how a prostate acutely inflamed and enlarged in addition to a chronic hypertrophy, the patient having complete retention, may, with rest and drainage, recover from the acute condition and urine again be voided.

Case IV.—This patient was sixty-two years old, and at the time I saw him passed no urine except by catheter. He suffered from a severe cardiac asthma and had the appearance of a man of seventy-five. Suprapubic permanent drainage was suggested, as a general anæsthetic could not be considered, and was agreed to by the patient and his family. About six weeks after the operation he voided urine naturally and has done so ever since. Dr. Wood tells me that he has perhaps an ounce of residual urine. The suprapubic fistula closed.

In those cases of prostatic obstruction with marked contraction of the bladder, if the gland is of the large variety, its removal undoubtedly produces a more roomy bladder. On the other hand, the removal of the very small, hard gland does little for the patient whose main trouble is his contracted bladder. A number of cases have been referred to me for some trouble of the bladder or prostate, the necessity for the removal of the gland being frequently suggested by the physician referring the Upon investigation the supposed obstruction is not found, the patient, frequently a man in middle life, having an enormous amount of residual urine, due to the loss of the bladder reflex from beginning locomotor ataxia. As the bladder reflex is frequently the first one to be lost in this disease, we should be constantly on our guard against surgical meddling with these cases.

I cannot close without saying just a word upon the routine use of the cystoscope in cases of enlarged prostate. When there is any doubt of the diagnosis, a suggestion of a new growth in the bladder, or stone that cannot be detected by the searcher, then it may be proper to use it. I believe, however, that many prostatics are subjected to needless pain and discomfort by the over enthusiastic cystoscopist.

38 ORANGE STREET.

ANTERIOR POLIOMYELITIS.*

By Irving D. Steinhardt, M. D., New York,

Clinical Assistant, Department of Orthopædic Surgery; Clinical Assistant, Department of Diseases of Children; Instructor in Charge of the Class for the Correction and Cure of Lateral Curvature, Vanderbilt Clinic.

Anterior poliomyelitis is an acute infectious disease and is sometimes known as infantile paralysis or atrophic spinal paralysis. It is also known under several other names, but I merely mention here the most common ones.

As to occurrence, I might mention that from 1890 to 1899 there were treated at the Hospital for the Ruptured and Crippled, in New York, a total of nineteen hundred cases, which makes an average of over two hundred new cases a year at this hospital alone.

Ætiology.—There is nothing definite known about the ætiology of this disease, although many theories have been advanced as to its predisposing cause, among which might be mentioned the following: Exposure to extreme heat, or cold, or dampness, or sudden change from the former condition to one or both of the two latter ones, causing a chilling of the body, and thereby rendering it more liable to the acute infection of this disease. Overfatigue is also offered as a predisposing cause, but for the reason that the overfatigued child is liable to seek rest in the first spot offered, which is very likely to be the more or less damp ground, and it will also bring about an abrupt change of temperature by copious draughts of cold water. Some observers assert that this disease is very apt to follow the various contagious diseases, but this is probably true only so far as these diseases lower the normal bodily resistance to invasion by destructive forces. Traumatism has also been mentioned as a factor. Ofttimes a child in apparent perfect health is affected. Boys seem to be affected more than do girls, and the negro race very much less than the white one. One attack seems to protect. Some observers have noted several cases in the same family. Children are most susceptible to the disease, which may occur any time during childhood, although most likely to occur during the first three years of life. Out of six hundred cases collected by Starr from his own records and those of several other observers, seventy-five per cent. occurred in the first three years of life, and of this seventy-five per cent. over half occurred during the second year. The actual exciting cause is unknown, but some very acute infection is to be regarded as the cause of the intense inflammation that is responsible for the destructive lesion in the cord. The disease, which is usually met with between late May and early October, may occur in isolated cases or in epidemic form. Such an epidemic occurred in New York and vicinity about a year ago, and is now the subject of a special investigation by a committee appointed for that purpose. I sincerely hope that their investigations will be very fruitful of results for the medical profession at large and therefore for our patients.

Pathology.—The primary pathological changes are in the spinal cord, and as these cases rarely die during or immediately after an acute attack, autopsies showing them are rare. The pathology of the disease, as I will give it here, is a composite picture drawn from the writings of several authorities. It is an acute inflammatory process of the area of grey matter of the anterior cornua supplied by the anterior spinal arteries. In the acute febrile form, which is from seventy-five to eighty-five per cent. of all the cases, actual inflammation is present, as is shown by the congestion, exudation of leucocytes, and serum into the perivascular and nerve cell spaces and proliferation of the neuroglia. In the others, the exciting cause is supposed to be a hæmorrhage or a thrombosis. Both the neuroglia and the cells are involved, and the result is a degeneration, pigmentation, and atrophy of the ganglion cells, and a corresponding increase of the connective tissue of the anterior cornua and of the adjacent. white matter, often with destruction of considerable portions of the horns, atrophy of the anterior roots, and distortion of the cord. In the early stage the motor cells become cloudy in appearance and later are swollen and lose their distinct outlines. Destructive changes affecting both cell and neuroglia take place. The grey matter shrinks, and the nerve fibres atrophy. This causes the spinal cord to become smaller at the seat of the disease, which is most common in the 'cervical and lumbar enlargements. With their nerve centres destroyed, the affected muscles lose their power and activity; and with the nerve fibres which have to do with the blood circulation in them also affected, and therefore their nourishment also destroyed, rapid atrophy takes place. Both of these facts are related in this atrophy which takes place. Very soon after the primary attacks, contractions and distortions take place in the affected parts, and the normal growth is markedly interfered with and retarded. In another set of cases, instead of a shrinkage and atrophy of the horns, there is found a gelatinous condition of the horns, they being replaced with young neuroglia tissue, with many branching cells and fine, delicate fibrils, resembling glioma. This gliomatous tissue may break down, forming a cavity surrounded by young neuroglia tissue.

There is no definite mode of onset. Sometimes an apparently well child at night is found in the morning to have had an attack and become paralyzed. In most cases, however, one may get general constitutional symptoms—fever, headache, chill, followed by sweating, vomiting, apathy or restlessness, diarrhoea or constipation; and during this last epidemic in New York, most of my patients gave a history of the latter; one may also find general hyperæsthesia over the entire body or affected members thereof, painful muscles and bones, which pains usually seem to be worse at night. In severe cases you may get very high and prolonged fever, ex-

^{*}Read, by invitation, before the Orange, N. J., Practitioners' Society, May 22, 1908.

treme prostration, prolonged unconsciousness, and even delirium and convulsions. And again, the symptom complex may be such as to lead to a diagnosis of cerebrospinal meningitis until the characteristic early paralysis appears. There are rarely any complications accompanying this disease, although it may come on in the course of some other illness

Diagnosis.—The question is often asked whether it is possible for a diagnosis of acute anterior poliomyelitis to be made at the onset. I must confess that such a diagnosis is very difficult, and most authorities say "no," absolutely; but on the appearance of the paralysis the diagnosis should not be in doubt any longer, except in very rare cases. And immediately steps should be taken to do all that we can to lessen the evil after results of this disease.

I have tried to put together here for your benefit a few early symptoms which might assist you in

making such an early diagnosis.

First: Sudden attack of high fever with vomiting without apparent cause, particularly after exposure to extreme heat or dampness, or sudden change of temperature, in children whose daily diet is poor in judgment rather than in quality, and particularly if this attack comes in the season for this disease, and one or more such cases are known to have occurred in the vicinity within a short time before.

Second: These symptoms following either diarrhea or constipation where no actual food infection can be decided upon as the cause of these symptoms.

Third: All of these symptoms, and apathy, restlessness, delirium, or convulsions, with marked hyperæsthesia over the entire body, limbs, or muscles, this being particularly suspicious if the disease is known to have occurred in the neighborhood.

Fourth: These symptoms plus the early loss of

reflexes, all or in part.

Distinctive Diagnosis.—In arriving at a diagnosis, after the paralysis has appeared, we have the follow-

ing conditions to distinguish from:

First: From paralysis of cerebral origin, the most common form of which is hemiplegia, and in which there is increased reflexes and stiff limbs instead of flaccid ones, and also in which the electrical reactions are not lost or changed. In this disease also convulsions may come first, and the intelligence may be impaired.

Second: From transverse myelitis, which, however, is uncommon in childhood, and in which the distribution of the paralysis is equal; the reflexes also are first increased, and the sensation affected.

Third: From Pott's paraplegia, in which Pott's disease would be present, the reflexes increased, and the distribution of the paralysis equal.

Fourth: From spastic spinal paraplegia, in which the distribution of the paralysis is equal and the

reflexes are increased.

Fifth: From rheumatism and other joint diseases, in which we would get redness, swelling, local heat, determine which it much but heat parallel sis, sweats, no interference with the reflexes, rigidity rather than flaccidity, one or more joints affected, age, etc.

I the Lean multiple nematic shields care in

young children and usually follows infectious diseases or metallic poisoning, and starts in the extensors of the hands and feet, has an equal distribution of the paralysis, and also with the sensation affected.

Seventh: From diphtheretic paralysis, in which there is a previous history of diphtheria, and in which the paralysis usually first appears in the muscles of the throat and neck, and is progressive, and which paralysis is preceded by a general weakness, long before the loss of power.

Eighth: From obstetrical paralysis or Erb's palsy, in which there is a history of the appearance of the paralysis at birth and the characteristic posture of the arm, with local anæsthesia in the distribution of

the circumflex nerve.

Prognosis.—The prognosis in this disease as to life is good. The amount of permanent damage is, as a rule, very much less than the primary paralysis which has appeared, as all the sections of the cord affected in the beginning are not permanently damaged or destroyed. Therefore, the ultimate result depends upon the extent of the permanent lesion in the cord, and the care and treatment which the case receives during the long season of partial recovery, and the treatment in the final stage. In the acute attack, if the advance of the paralysis remains stationary for twenty-four hours, it usually indicates that the maximum of the paralysis has been reached. In the early stages of the disease, the final degree of paralysis may be somewhat nearly correctly estimated by the following: When the faradic irritability is lost at once in the affected parts, the paralysis will probably be permanent. When lost later, gradual recovery will take place up to a certain point, depending upon how late the faradic irritability has been lost. It may also be estimated by the so called reaction of degeneration. About a week after the initial paralysis, the faradic current reaction in the muscles and nerves directly dependent upon the diseased area of the cord is lessened and soon lost. If the faradic reaction is retained, or merely diminished, the chances are good for ultimate recovery. The muscles which have lost their faradic contractibility may still be made to react to the galvanic current. In normal muscles the reaction is greatest at the closing of the negative pole. In the paralyzed muscles, the reaction is slower, it requires greater stimulation, and the contraction is greater at the closing of the positive pole. This is the reaction of degeneration. The muscles showing the reaction of degeneration are those which are going to be permanently affected. According to the extent of the permanent lesion in the cord and to the group or groups of muscles either wholly or partially paralyzed and to the care and treatment received by the affected parts during the acute, subacute, and chronic stages of the disease, is the future loss of function, contractions, and deformities going to depend upon. In the distribution of the paralysis of this disease, the lower extremities are more often affected as against the upper extremities in the proportion of about eight to one. The right leg is affected about as often as the left leg, and in a very large number of cases both legs are primarily and may be permanently affected. This is true of the upper extremities also. The abdote tail muscles, the back muscles, the cervical muscles, and the muscles of the face may also be affected in whole or in part. The paralysis may affect all four extremities, may be general, or may be in any number of different combinations. Should death occur in this disease, it is usually caused by a

paralysis affecting the respiratory muscles.

In the lower limbs we may have two types of paralysis, the thigh type and the leg type. In the thigh type, the psoas, iliacus, glutæi, and the muscles about the thigh are chiefly affected, while those on the inner side of the thigh and below the knee often escape. In the leg type, the peronei alone or in conjunction with the anterior tibial group of muscles may be combined, and sometimes the posterior tibial group also. The leg and thigh type may be combined in some cases. In the upper extremities we may have an upper arm type or paralysis affecting the muscles about the scapula, also the deltoid, the biceps, and the supinator longus, and a lower arm type of paralysis which affects the muscles below the elbow, either the flexors or the extensors, but in which the supinator longus escapes. We may also have a combination of these two types.

From within a few hours up to a few days after the acute onset, the paralysis may become apparent. The entire body and extremities may be affected within this time, also the face and neck. This first paralysis is usually greater than what permanently remains. For a while after the constitutional symptoms have abated, there is a period during which the paralysis remains stationary, and then comes the beginning of a period that ultimately ends in the partial recovery from the primary paralysis. period lasts all the way from six months to a year, and sometimes even longer. It is due to the fact that as the congestion and exudation recedes in the spinal cord, the motor cells and their connections which have not been entirely destroyed take up again their active functions. Where the cells and their associate tissues have been entirely destroyed, atrophy of the muscles supplied by them goes on more rapidly. Sensation, however, even in the worst cases, is rarely if ever affected. From this stage of partial recovery, we go to the stage of chronicity; and now without the proper treatment comes distortion, deformity, cold, flaccid, flail like limbs, retardation and stunting of normal growth, impaired motion, etc.

Prophylaxis.—Before giving the early and late treatment of this disease, I wish to say a few words as to its possible prevention. Can it be prevented? In view of our imperfect knowledge as to the cause of this disease, it is hard to give definite prophylactic advice, but we can caution mothers not to permit their children to expose themselves to the extreme heat of the midday in the hot summer months, and to see that those in charge of the children do not permit them, after being fatigued by play, to throw themselves down for rest on the cold ground, or to plunge into cold baths, or to in any other way assist in chilling the system, lowering the normal body temperature, and resistance to infection. We can see that infants and children are fed in a normal, rational way with the proper food suited to their age and development at the proper intervals, and are not allowed "to eat anything at any time and at any place." We can further caution the mothers against over fatigue, and the necessary regulation in

a proper manner of the child's bowels. I think that at the present time this is about all we can offer our patient in the way of prophylactic advice, unless, in the course of an epidemic, we suggest that they keep their children separate from others in

whose family the disease may exist.

Treatment.—As we go on to treatment of this disease, we may divide it into three stages, the immediate, the chronic, and finally the operative treatment for the correction of such loss of function or deformities that it may be possible to correct by such operative treatment. In the acute stage, the treatment is solely symptomatic. If the diagnosis is made early enough, measures should be taken that will tend to relieve the spinal congestion. This will be the administration of a brisk laxative, sedatives of a mild form, counter irritation to the spine by means of dry cups, iodine, the Paquelin cautery, mustard every three hours to slight reddening; or an ice bag may be applied to the spine. Free perspiration may be brought about by hot baths, and frequent sponging with cool water, or a simple fever mixture may be used to reduce the high temperature, if it is present. The patient should rest in bed in a lateral position preferably, as lying on the back continually simply adds to the stasis in the cord. As soon as the affected parts can be mapped out, they should be wrapped in cotton, and artificial heat applied, if necessary, to keep up the normal temperature of the part. The patient should have a light, but very nutritious diet, and just as soon as the acute symptoms subside, regular and systematic treatment should be instituted to care for the affected parts. The better this treatment, the better the final result to your patient, and I believe that these patients do better in the hand of the orthopædic surgeon than they do with the neurologist. This treatment should have for its object the maintenance, so far as it is possible, of the nutrition of the affected parts, the prevention of contractions, and the relief of strain upon the weakened tissue, so that deformity may be prevented. This can best be done by the administration of a tonic such as strychnine in doses sufficiently large to cause muscular irritability, which, in this disease, of course, must be tested for mechanically, as in the paralyzed muscles, twitching and stiffness in the back may not be observable. Early in the disease also, as the acute symptoms subside, a light, general massage may be instituted, gradually increasing to deep, thorough massage as time goes on. Muscle friction and muscle beating, heat and electricity and hydrotherapy may all be used to good advantage. electricity to be used, however, is that of the galvanic current, and it can only be used with advantage up to the time that it will cause muscular contraction in the affected parts. After that time I believe the use of it to be "love's labor lost." formity may be prevented by moving each joint to the limit of its normal range of motion in all directions each day, morning and evening, and supporting the limb with appropriate apparatus in its normal positions. In young children, up to about two years of age, where the lower extremities are affected, if the case is seen early enough, after the acute symptoms have subsided, and before deformity has set in, they are best treated by being put upon a Bradford frame modified by a slight device

which prevents contraction, through the normal muscles working against the paralyzed ones, and which also holds the limbs in a slightly overcorrected position; in older cases, of course, this treatment would be impractical, and therefore the application of a proper brace is necessary to prevent contraction deformities. There are a number of these braces, each one suited for a particular phase of the paralysis in the part affected, and I shall not discuss them here, as I would have to take up in detail the different forms of the paralysis and the brace suitable for each, and I do not believe such a discussion would prove either interesting or profitable to you at this time.

The third stage of the treatment is the operative one, and the most important of this class are tendon transplantation and arthrodesis. The object of tendon or muscle transplantation is to utilize the muscular power that remains in a paralyzed part or parts to the best advantage. It was first performed by Nicoladoni in 1882 for the relief of a paralytic calcaneus. He divided the tendons of the peroneus longus and brevis behind the external malleolus and united the proximal ends to the distal extremity of the divided tendo Achillis. Parish in 1892 sewed the tendon of the extensor proprius hallucis to that of the paralyzed tibialis anticus for the relief of paralytic valgus. In some cases in which a muscle has been paralyzed the tendon of the paralyzed muscle has been divided and its distal end has been united with the tendon of a normal muscle, the normal tendon having been split to receive it. In 1898 Eulenburg reported a case in which the deformity was a pes equinus. He gave relief in this case by tendon implantation. He took one half of the tendo Achillis and part of the tendon of the solæus and implanted them upon the tendon of the peroneus longus et brevis, and then divided the other half of the tendo Achillis. This was a transference of the function of the flexors to the pronators, and gave quite beneficial results in this instance. It has also been pointed out that when a muscle or its tendon is sutured to a paralyzed antagonistic muscle, the transplanted structure will actually execute the functions of a paralyzed muscle, mental activity, and practice with the muscle in its new capacity bringing about the desired result after the operation.

Of course any operative procedure is contraindicated while spontaneous recovery is going on; also in neglected cases where distortions have taken place through muscular contraction, until these deformities should be corrected and the normal muscles toned up by massage and the usual method of treatment and gotten into good condition.

To obtain the best results a thorough understanding of the muscular movements of the part to be operated on, and the most important of these movements is very necessary, regulates the degree of success which your operation is going to have in benefiting your patient. A foot, for example, is better placet in a position which would allow it to be brought to a right angle with the bones of the lower leg and adducted, rather than the reverse of this. It is also advisable to choose the muscles which will help in the prevention of deformity and aid to correct the same if it exists, as well as assisting in the

restoration of lost functions. A normal weak muscle must not be chosen to do the work of an originally strong but now paralyzed one, if one of equal strength can be so manipulated as to be of service. But if a weaker one must be used, its lesser normal function should be sacrificed to its newer and more important one if the same be deemed advisable to the success of it in its new capacity. Each case must be worked out by itself, and I therefore will not go into details of the various combinations which have been suggested and used, but only say that I believe the simpler the operation, by which I mean not attempting to do too much, the better the result is likely to be.

The technique of the operation is very simple, and if done under an Esmarch bandage the field of operation is very much clearer and cleaner to allow of good work. It is essential that in the limb to be operated on there should be no restriction to normal motion. The incision should be such as will expose the point of attachment of the tendon to be transplanted and the muscular substance, and this also allows you to verify your previous idea as to what are the partially and which the totally paralyzed muscles by sight. Paralyzed muscle looks dull and yellowish red, with a whitish yellow ten-don, and is much atrophied. The next step in the operation is to slit open the tendon sheath and divide the tendon near its point of insertion. Take this divided part and attach it to the freshened surface of the paralyzed muscle, which has been made taut by one of several means, with silk sutures, then cover the graft by uniting either the tendon sheath or fatty tissue over it with fine catgut. incision is best closed by a continuous catgut suture. The part is then put into an overcorrected position and fixed there by a plaster of Paris bandage, after which a corrective brace is used for several months more, in conjunction with, massage and like treatment, looking to the development and welfare of the affected limb, and to strengthen it in its new position. Several modifications of this operation are now in vogue for use in various parts of the different extremities.

The other operative treatment, known as arthrodesis, or the removal of the cartilaginous surface from articulating bones, may also be employed in a certain number of cases, to cause ankylosis of the joint after putting the same in a good position for use. The operation consists in opening the joint, removing the cartilaginous surfaces of the opposing bones, and, after closing the wound, putting the limb in plaster of Paris until union is secured. In some cases tendon transplantation and arthrodesis may be employed together with advantage. Some authorities are advocating the transplanting of nerves also for use in these cases, but as yet I do not believe the results obtained warrant me in advising it for use

In closing my paper, I wish to acknowledge my indebtedness to the works of Dr. Whitman, Dr. Young, and to Dr. Bradford and Dr. Lovett's on Orthopædic Surgery, and to Dr. Delafield and Dr. Prudden's work on Pathological Anatomy and Histology, to Dr. Holt's work on the Diseases of Children, and to Dr. Start's work on Organic Nervous Diseases.

ACUTE ANTERIOR POLIOMYELITIS IN. THE ADULT, WITH EXHIBITION OF CASE.*

By LASALLE ARCHAMBAULT, M. D., Albany, N. Y.,

Lecturer on Neurology, Albany Medical College.

Poliomyelitis anterior acuta (a term we owe to Kussmaul), or infantile paralysis, as it is more commonly called, is a disease common enough in children, one of which every member of our society, I have no doubt, has seen several instances. I know of no commoner organic affection of the spinal cord in infancy and early childhood. But, in the adult, poliomyelitis anterior acuta is rare, the degree of its rarity at this period of life exceeding by far that of its frequency in childhood.

In Muller's statistics published in 1880, and based on the study of forty-six cases, only three of the cases were in adults; a percentage, therefore, of

Of the eighty-five cases collected by Baumann at the University Clinic of Breslau between 1889 and 1904 and reported the following year, only two occurred in subjects over ten vears of age.

Dana, however, in his remarks upon the epidemic which occurred in the Otter Creek Valley, Vermont, and which was reported more particularly by Mac-Phail and Caverly, maintains that the percentage of adults affected was as high as ten.

It is not without reason, therefore, that I deem myself fortunate in being able to present to you on this occasion a perfectly typical case of infantile paralysis in a man who has reached his fortieth vear.

As you shall see from the following data regarding both the mode of onset and the objective symptomatology, the clinical picture which this patient presents can hardly be any other than that of well characterized poliomyelitis anterior acuta.

History of the Case. Mr. G. G. H., age forty, married; knitter by occupation. His past history presented nothing of immediate inter-

est to us in the study of his actual condition.

Save for a certain degre of dizziness during the two weeks preceding the onset of the disease, the patient was enjoying relatively perfect health at the time he was taken

On Friday, August 9th, while at work, as usual, he began to suffer from headache, which rapidly grew in intensity and became so severe that the patient spoke of it to-day as the most agonizing pain he had ever experienced and one he should never forget. In the evening of the same day, fever appeared and rapidly increased during the might, so that the following morning the patient was totally confined to his bed. To the prostration resulting from high fever and persistent intense headache was soon added the discomfort occasioned by severe spells of vomiting. For four days, this triad of symptoms continued without any remission, sapping the patient's strength and minimizing his power of resistance to the final and most terrific blow of the infectious invasion. There had been up to this time no trace of paralysis or of subjective sensory disturbances.

It was on the morning of Wednesday, August 14th, the fifth day, therefore, after the appearance of the initial headache and pyrexia, that the patient noticed, on awaking, that he had totally lost the use of his left arm; his right arm still possessing at this particular time its usual strength. The following day, numbness and tingling appeared in the right leg, after which there developed a very gradually increasing paresis of both lower extremities, involving the right one, however, decidedly more than the left. It took three days for this paralysis to become fully constituted, i. e., to attain its maximum intensity in

this particular case.

After the onset of these paralytic manifestations, the lower extremities were also the seat of severe pains of a burning character, radiating over the entire length of the limb from hip to foot, most severe in the sole of the foot and much more marked at any one point in the right than in the left extremity. Pain of equal severity was also present along the spine, more especially in the lumbo-sacral region and at the nape of the neck. Coincidently with the development of motor paralysis in the lower ex-tremities, the right arm began to show evidence of in-volvement and gradually became disabled, more especially in its proximal segment (shoulder and arm).

The face had at no time been implicated, but the same could not be said of the muscles of the neck and trunk. The patient told us, indeed, that at the onset, whenever his position was changed from the fully recumbent to the sit-ting posture, or the shoulders raised from the bed, the head, unless supported, would fall as an inert mass either forward on the chest or backward on the bed, as the case might be. As to the trunk muscles, they were at one time so widely involved that the patient lay perfectly helpless on his back, totally unable to sit up or turn to either one side or the other, and that even to-day he can only partly

roll over to either side, being able to resume his original position only when he has turned to the left.

As regards involvement of the organic reflexes, there was this point to be noted, that immediately following the onset of the paralytic symptoms in the lower limbs, complete retention of urine existed which necessitated three or four catheterizations. But there has been since then no

further disorder of the organic functions.

Actually, physical examination revealed the existence of a widespread motor paralysis affecting all four extremities—of a paraplegia, in other words. This paraplegia was, although not obviously so, symmetrical in its own peculiar fashion, as we shall see shortly.

If we study more minutely the topography of this paralysis in each extremity individually, we see that in the right upper extremity the paralysis involved mainly the adductors and abductors of the arm, the flexors and extensors of the forearm, the pronators and supinators of the forearm and hand, but that the various groups were very unequally affected; the abductors, extensors, and pronators being appreciably weaker than the adductors, flexors, and supinators.

The muscles of the shoulder girdle had preserved practically their full strength, and the patient could move the shoulder in almost any direction; the excursion was ample the movement powerful. The small muscles of the hand and fingers were very slightly involved; the majority of the finer movements being executed readily and with relative

Resistance to passive motion was very poor in any part of the extremity save at the shoulder, but the patient could execute voluntarily many of the movements; he was totally unable, however, to raise the elbow from the bed, and extension of the forearm on the arm is an extremely laborious task.

The left upper extremity was disabled practically in its entirety. There was no motion whatever in the shoulder and arm, none in the forearm, except a slight degree of supination and a trace of pronation. Flexion of the hand at the wrist was the only coarse movement executed with perceptible amplitude, extension being decidedly feeble. The small muscles of the hand and fingers were the least involved; the fingers could be moved separately and the thumb approximated with any of them, but nevertheless they were weak. The hand showed considerable atrophy and was assuming the attitude known as the main en griffe.

The right lower extremity paired with the left upper as regards extent of involvement, there being paralysis of almost every muscle in the limb; but this paralysis was unevenly distributed. It was complete in the muscles of the leg, foot, and toes; incomplete, though marked, in those of the root of the member. Thus, the patient could, when lying on his left side, partly flex the thigh on the abdo-

Read at the first annual meeting of the Third District Branch Medical Society of the State of New York, held in Albany, Octo

Meyer in 1861 and Duchenne in 1872.

men; a movement which was impossible, however, in the dorsal position. When lying in this latter posture, the leg was invariably held flexed at the knee, and one would naturally suppose the flexors of the leg to be intact, when, in reality, they were almost totally disabled; flexion being brought about passively with the help of the other leg and to secure comfort to the patient. Full extension (itself simply the result of gravity) caused intense pain, as it placed on the stretch an inflamed sciatic nerve trunk. Adduction of the thigh was relatively good, abduction very The patient was absolutely unable to lift the foot

The left lower extremity was, of all four, the least affected. The various movements of the thigh and leg, although distinctly weaker than normal, were relatively well preserved and powerful, but in the foot and toes motion was as seriously compromised as in the other extremity.
As regards the trunk muscles, those of the thorax, abdo-

men, and perinæum were entirely free, but those which constituted the fourth and fifth layers of the back, the erector and multifidus spinæ more particularly, were decidedly implicated; the patient being unable to sit up in in bed or to resume, except by the intermediary of gravity, the recumbent posture when propped up.

The muscles of the neck, once markedly incapacitated,

have practically regained their former strength.

There were no objective disturbances of any of the various forms of superficial and deep sensation in any part of the body, save a generalized, though slight, hyperalgesia. But subjective sensory phenomena, on the other hand, were not wanting, and the pains in the lower limbs, which were so distressing at the onset of the disease, although much lessened in intensity, still continue to annoy the patient. Similar pains were felt at the nape of the neck and in the left arm. Moreover, there was a generalized muscular tenderness, more marked in some parts than in others, and which, in the lower extremities, was in great part confined to the course of the larger nerve trunks. It was most evident in the right leg, for instance, wherever the sciatic nerve trunk and its external popliteal continu-ation was more accessible (middle line of posterior surface of thigh, popliteal space, head of fibula, external surface of leg, external malleolus, etc.); suggesting, therefore, implication of the main trunks rather than of their intramuscular ramifications. In support of this hypothesis was the absence of these phenomena in the muscles of the anterior femoral and posterior tibiofibular regions, and the fact that this tenderness was by far most marked in those extremities which are the most paralyzed; as if the neuritis were simply of a radicular character, an extension from the central focus in the spinal cord. And yet, relatively slight pressure exerted upon the plantar surface

relatively slight pressure exerted upon the plantar surface of either foot caused considerable pain.

All the tendon reflexes were abolished in left upper and right lower extremities. In the right upper a slight radial reflex was obtained, but no trace of a tricipital response exists. In the left lower extremity the knee jerk was, perhaps, rather lively, but the tendo Achillis jerk was very faint if at all present, a doubtful response being occasionally observed. The umbilical, cremasteric, and plantar cutaneous reflexes were present

As to the existence of trophic disturbances the marked muscular atrophy in the whole of the right lower extremity was most evident; the volume of the left limb was relawas nost evident; the volume of the left limb was reastively well preserved. In the upper extremities the atrophy, though distinct, was far less appreciable on inspection; it was more marked in the left than in the right limb. Dr. E. A. Bartlett, to whose well known skill the electrical management of the case had been confided, reported that a partial reaction of degeneration was present; it was fairly generalized, but, as might be expected from the data regarding the distribution and degree of functional inadequacy and trophic disorder, this reaction likewise was most

Vasomotor disturbances consisting in coldness, both sub-

perior disturbances consisting in countess, both subjective and objective, were also to be noted, affecting more particularly the right lower limb.

Deformities were, of course, hardly to be expected, on the potential of the phase of of th appreciable deviation of the vertebral axis.

We have the co, there with a side pread atrophic not appeal a machine " nome remittes in a man of forty years of age. Among the many points which need further discussion in this case, the first one, naturally, is that regarding the correctness of

The majority of authors, among whom I may mention Déjerine, Marie, Oppenheim, and Osler, are of the opinion that a certain number of the cases reported as "poliomyelitis anterior acuta in the adult" were truly instances of peripheral neu-The following passage taken from Déjerine and relating to the differential diagnosis between poliomyelitis and peripheral neuritis, is of particular interest to us, as it is almost an exact résumé of the atypical features present in our case and which the author evidently considers sufficient to establish the diagnosis of polyneuritis. He says: "In the adult, one may observe atrophic paralysis, acute in onset, and the course and general evolution of which simulate more or less closely those of infantile paralysis. Many of these cases come under the head of neuritic muscular atrophy. Others, few in number, do seem to be truly instances of acute poliomyelitis; but, thus far, pathological anatomy has not furnished absolutely demonstrative proofs of the existence of the latter category of cases.

"In muscular atrophy of spinal (medullary) origin, the limbs and nerve trunks are no more sensitive to pressure than in health; whereas, in cases of muscular atrophy dependent upon neuritic lesions, there is generally present a condition of true hyperæsthesia, which is very marked, indeed, and characterized by subjective pains either of a lightning or boring or simply neuralgic character, as well as by very severe pain on pressure upon the nerve trunks and muscular masses.'

Antagonistic to our diagnosis as this passage from Déjerine may seem, we do not feel disconcerted, as there still remain many features about this case which are not to be explained by a peripheral neuritis. This latter lesion could not possibly account for the abruptly appearing and massive atonic paralysis of the left upper extremity or for the transitory involvement of the organic vesical reflex. No neuritis, however rapid in its evolution, could explain the development in less than a week, of a paralysis of such formidable extent (all four extremities, trunk and neck) and at the same time of such generalized severity as that which this patient presents; nor would it explain the rapid occurrence of such widespread degenerative atrophy. Still, there unquestionably exists in this case a considerable degree of nerve involvement, and the next question is How are we to explain it? Is it to be considered as an independent and merely coincident lesion, or rather as part and parcel of the medullary affection. i. e., simply as an extension of the process having originated in the cord? In the former case, it would seem rather peculiar that a strictly systematized motor neuritis (there being absence of all objective sensory disturbances) should evolve independently from, and still coincidently with, a medullary lesion which is itself absolutely confined to the motor neuron. We are all the more shaken in our belief of such a probability, because the manifestations of this very neuritis appeared at an appreciably later date than the paralysis, after what we believe to have been poliomyelitic lesions had determined

first a paralysis of the left arm and two days later

a paresis of both lower extremities.

In the presence of such facts, we are led to consider that in the pathogeny of this clinical picture there is an association of poliomyelitis and neuritis. The word association in this connection, however, is most objectionable, as it at once suggests the existence of two lesions, whereas, in our mind, there is but one, namely, a lesion of the peripheral motor neuron; the lesion in this case having involved the neuron in its entirety, as the result, very probably, of the unusual virulence of the primary underlying infectious process. Between this case and the usual type of acute anterior poliomyelitis, there is only a question of variation in the extent of involvement of the peripheral motor neurone. Anatomically, we might designate the lesions in such a case as this, by the term inferior motor neuronitis (neuronite motrice inférieure); a term we owe to Juarros and which Brissaud and his pupils have already applied to cases which, in many respects, resembled that which we have the honor of submitting to your consideration.

That in its application to this particular case, the term neuronitis is not only fully justified, but that it even represents the only appropriate designation, is amply demonstrated by certain other facts in the history of the development of this clinical picture; facts which, at the same time, give us an insight into the mechanism of production of this neuron-It will be remembered, indeed, that the disease was ushered in by the cardinal symptoms of meningeal inflammation, headache, vertigo, and vomiting, associated with pyrexia, and that this characteristic triad constituted the entire symptomatology of the affection for fully five days. The significance of this onset is unquestionable, and it is hardly necessary to mention the occurrence of severe rachialgia one or two days later, in order to assert that the initial lesion in this case was undeniably meningitis. This supposition, moreover, finds additional support, when we come to explain the full development, in two days, of a poliomyelitis having a vertical extent limited above evidently by the first cervical segments and below by the conus medullaris. Such rapid extension of inflammation cannot take place within the cord, but must almost necessarily do so without it, through the intermediary of the blood stream, and therefore in the leptomeninges from which the cord receives its blood supply. It then becomes readily conceivable that from the meninges the infectious process could have traveled along the vessel walls and penetrated into the substance of the anterior gray matter; likewise, it can easily be imagined that the process has further gone in the opposite direction and also involved the spinal nerve roots, by simply extending along their sheaths, which are nothing else but tubular prolongations of the meningeal coverings of the spinal cord. Thus does the rapid development of a meningoradiculomyelitis find a simple and logical explanation. It goes without saying that the onset of the disease in this case, by the character, severity, and duration of its symptoms, strongly militates in favor of the infectious character of poliomyelitis anterior acuta; a fact, moreover, which to-day is almost universally accepted. In this connection it

might be stated that the bacterial origin of poliomyelitis has been recently advanced by a few observers, and is actually attracting considerable attention. Already in 1901, Delhloff had cultivated. a diplococcus from the cerebrospinal fluid of subjects suffering from the disease, and he has more recently (1906) come back upon these facts, confirming the results of his earlier researches. The organism varies somewhat in its reaction to the various culture media upon which it is grown, but under the microscope, its morphological aspect is always the same. It bears no resemblance whatever to the pneumococcus. In 1903, Raymond and Sicard suggested the possibility of an intimate relationship between the ætiological factors concerned in the production of poliomyelitis and cerebrospinal meningitis. Many authors, however, consider that the moment has not yet come for the acceptation of such a generalization. Schultze's case of infantile paralysis, in which the meningococcus was detected, is far from conclusive.

P. Morvan, in his excellent *Thèse de Paris*, July, 1905, upon poliomyelitis anterior in the adult, remarks that in the etiology of the affection no recognized species of microorganism can be mentioned;

the toxines suffice for its determination.

Yet Geiersvold in 1906, writing about the epidemic of poliomyelitis in Norway during 1905, states that on several occasions peculiar organisms were observed in the cerebrospinal fluid of individuals presenting the disease.

Evidently the bacteriology of poliomyelitis anterior acuta is still in the hands of the future.

The question of the association of poliomyelitis and meningitis, however, is one which is rapidly passing out of the field of controversy. Several instances, indeed, are on record (Brissaud and Londe, Triboulet and Lippmann, Raymond and Sicard. Achard and Grenet, Guinon and Paris, etc.) in tile paralysis, an abundant lymphocytosis; a fact which may be considered proof positive of the existence of a meningitis. In Guinon's case, moreover, there existed clinically other signs of meningitis (Kernig's phenomenon, dermographia, etc.). More recently, the cases reported by Cruchet (1906), by Camus and Sézary, Raymond and Lejonne (1907) have furnished important additional clinical evidence of the participation of the meninges in the poliomyelitic process. Anatomically, the meningeal involvement in poliomyelitis was described several years ago by Schmauss and by Goldscheider.

Naturally, in our case, lumbar puncture would constitute a most simple means of ascertaining whether or not a meningitis exists. The practical importance of this procedure had not escaped us, and if it has not yet been resorted to, it is mainly because we were unwilling to stake our opportunity of presenting the case to you. The operation was simply deferred, and we expect to proceed with it within the next few days. Whatever share the lesions of the meninges and nerve roots may have had in the production of this clinical picture, the fact remains that the anatomical substratum of this extensive atrophic paralysis is constituted essentially by a poliomyelitis involving almost the entire length

of the spinal cord from the superior cervical region to the conus medullaris.

As an instance of poliomyelitis, this case pre-sents still a number of interesting features. In the first place, we notice that, although the four extremities are affected, the left upper and right lower limbs are involved to a decidedly greater extent than are the remaining two; in other words, it is, although not purely so, a crossed spinal paralysis, and thus illustrates the fact upon which Marie, among others, has particularly insisted as early as 1892, namely, that when poliomyelitis involves one lower and one upper extremity, the paralysis is more frequently crossed than unilateral or hemiplegic in type. In our case, all four extremities being involved, we cannot speak, of course, of a crossed spinal paralysis in the classic sense, but, nevertheless, the relations are preserved as regards distribution of proportionate degrees of paralysis. In addition to a crossed paralysis there exists in this case a crossed paresis.

The age at which this disease came on, the patient being actually in his fortieth year, is a feature of considerable interest. As far as I have been able to ascertain, there is no case on record of poliomyelitis in the adult in which the affection appeared later than in the thirty-third year; such was the age of the patient presented by Huet and Lejonne before the Neurological Society of Paris at the meet-

ing of May, 1906.

A fact to be wondered at is that the patient has survived this virulent invasion, being given the meningitic character of the initial phase, and the rapid involvement of almost the entire musculature of the body, even to the muscles of the neck; a feature closely suggesting Landry's paralysis. It is remarkable that the process should have stopped just short of invading the bulbar centres.

Of cases which at all resemble ours, literature affords but very few examples. Brief consideration may be given to the following cases carefully re-

ported within the last two years.

In the case presented by Huxt and Leionne, the patient, a man of thirty-three, had had for a whole week previous to the onset of the paralysis a febrile condition associated with severe headache. Then there suddenly appeared a paralysis of the left lower extremity, and three or four days later the left and then the right upper extremities rapidly became disabled. There were no objective sensory disturbances, but the patient complained of pains along the entire length of the spine, especially at the nape of the neck and in the lumbosacral region. In the lower pain, this tenderness being found along the course of the anterior crural and sciatic nerves on the left side and limited to that of the sciatic on the right side.

Raymond and Lejonne report the case of a young woman, of twenty-two years, who, after twenty-four hours of high fever and violent headache, noticed on awaking that she had lost completely the use of the right lower One or two days later the left limb also became disabled, and at the same time the patient began to experilocalized, not radiating over the whole extremity, and lasted for fully six weeks. There was at no time any appreciable disturbance of objective sensibility, but there did exist at all times a marked muscular tenderness in the On the other hand, the nerve trunks were totally insensitive to pressure. The organic reflexes remained intact throughout. Lumbar puncture was not performed, but the

simply from the clinical picture, to the existence of a meningoradiculitis in addition to the poliomyelitis,

More recently, Claude and Chartier have produced the detailed history of the interesting case which follows:

A young girl of seventeen, who, for a year past, had been employed as saleswoman in a large department store, constantly standing therefore and often exhausted at the end of her day's work, was taken suddenly ill with high fever, headache, rhachialgia, and mild bronchitic symptoms. This condition having lasted five days, the patient, feeling somewhat better, decided to leave her bed, but had to resume it at once, owing to her extreme weakness. The following morning she awoke to find herself totally incapacitated, having lost the use of all four extremities, of the muscles of the trunk and neck, and being even handicapped as regards respiration. The muscles of the face, pharynx, and larynx alone had escaped. There was some stiffness about the neck which continued for a few days more. Five days after the onset of the paralysis there developed in all four extremities and along the whole spine very severe lancinating pains which kept the patient in a state of constant distress. The slightest pressure upon the muscular masses likewise caused very considerable discomfort, as would also any passive movement of the limbs, flexion more particularly. The subjective sensory phenomena later disappeared, for the most part, but there persisted a marked tenderness on pressure, both in the muscles and in the nerve trunks. There was at no time any appreciable objective disturbance of either superficial or deep sensibility. At the onset of the disease there was retention of urine which lasted two or three days. Lumbar puncture performed at this period revealed the presence of no abnormal

Such are the salient points in the history of this most interesting case, which represents, to the best of our knowledge, the only instance on record of a clinical syndrome analogous to that which we have had the good fortune of bringing to the attention of the Society.

In terminating, I desire to express right here my highest gratitude to Dr. George Lempe, to whose courtesy I owe the privilege of this presentation.

126 EAST THIRTY-FOURTH STREET.

MALARIA IN GREECE.*

By A. Rose, M. D., New York.

Cardamatis describes a malarial epidemic in Athens:

Towards the east from Athens, between the northeast foot of the Hymettos and the Lykabettos, there are two extensive quarters, Batrachonissi and Ampelokipi, where; since the year 1880, the infantry barracks and many other public and private buildings have been erected. To the east from Ampelokipi there are two other smaller quarters, Goudi and Kandrebiati. These outskirts of Athens, which are hilly, have a surface of 550 acres, and are 85 to 134 metres over the surface of the sea; they are crossed by two rivers and some rivulets which confluent and form the Ilissus. The latter, assuming only after heavy rains a formidable size, crosses the whole described landscape and runs into the Phaleron. The geological condition of the soil is about the same as that of the Attic soil in general. Batrachonissi has very friable, loose marl; Ampelokipi, Athenic slate, covered with a deep layer of diluvium; in Goudi there are sporadic layers of red muddy ground. On account of this geological condition the landscape described is, in consequence of the permeability of the layer of diluvium, dry on the surface and only much infiltrated after heavy rain, except Goudi, with it rocky ground, here the ground water is less deep under the surface. In general, water is found evervwhere in small depth; the inhabitants draw it from wells, make use of it to water the garden, and as it is without any after taste, for drinking and cooking. With the dryness of the soil on the one hand and its chemical condition on the other hand, the vegetation is in general poor, only in Ampelokipi and in Goudi somewhat more cultivation is done; here there are vegetable, flower gardens, orchards, orange and wine plantations; in some parts cereals are raised, especially barley.

In the year 1901 an epidemy or rather a pandemy of malaria broke out in these quarters; about two thirds of the inhabitants and the soldiers in their barracks were attacked. Of ninety-two men of the company of telegraphists, stationed at Goudi, sev-

enty-nine took sick with malaria.

The epidemy began during the last ten days of the month of July (middle temperature at time time 27.82° C., 82.08° F.) in Ampelokipi and Batrachonissi, and spread also among the neighboring population. It is evident that the confluence of and stagnation of water from a number of rivulets was

the cause of this epidemy. At first the cases of malaria appeared sporadically, but they became numerous after continual rain during the ten days of the first part of the month of August, and attained their maximum of intensity with the 20th day of August (middle temperature 24.21° C., 75.60° F.), until the end of the month September (average temperature 23.82° C., 75° F., during the first ten days, and 20.85° C., 69.68° F., during the last ten days of this month); with the first days of the month of October (average temperature 19.51° C., 67.8° F.) new attacks became less numerous, while relapses were frequent. A shower of rain, on October 12th, lasting twelve hours and thirty seconds, with 13.3 mm. precipitation, caused a rapid sinking of temperature of the atmosphere to 12.55° C., 54.5° F. Cases of malaria of first invasion became more and more scarce and ceased almost completely during the month of November.

The malarial epidemics which appeared in the same localities during the years 1902 and 1903 were

of much less intensity.

Investigations revealed that it was only one species of mosquito, namely, Anopheles superpictus, which multiplied in the epidemic zone. It was found that the principal place where the development of innumerable swarms of this kind of mosquito happened was a branch of the Ilissus, named Phlebes, which had been dry during about twenty years, but had been running again in intervals during spring, summer, and autumn of the year 1901. The same was the case with other branches of the Ilissus passing through Goudi and Ampelokipi, and which, on account of the unevenness of their beds, formed, after heavy rains during the month of August, small swamps upon which the mosquitoes prospered. According to the observation of physicians and inhabitants there had been at no time in former years such an enormous number of cubicides. As a rule, it is very dry during the summer in Athens, while the contrary was the case during the summer of

The superpicti which had developed during the spring did well in immense numbers during the summer and autumn, thanks to the rainfalls during June and August, in consequence of which the Ilissus had water stagnating within and alongside of the riverbed, affording protection to myriads of mosquitoes.

Besides the excessive rain which preceded the development of the epidemy, there happened to be another factor, namely, extensive digging of ground which had been done for the construction of several

new roads.

During the two following years, 1902 and 1903, there had been some rain during the spring and summer, and a considerable number of mosquitoes were observed, but the malaria epidemy was of much less intensity.

During the spring of the year 1904 it was also rainy, and mosquitoes developed correspondingly, but they disappeared almost completely during the summer; it was perhaps that north winds, which reigned during this season, drove them far away from the city. It was noticed that relapses were numerous in the epidemic zone of the succeeding years, attacks of first invasion, however scarce, con-

[&]quot;This article is a continuation of Dr. Rose's article on Malaria in Green, public of in the Fanorial of April 11, 382-381, 168 which the reader is referred. The author takes this opportunity to correct an error of his in the first article. It was not Dr. Cardamatis, hit Pr. Sabba, who was the feather of its Sp. Dr. Cardamatis was and is the principal cooperator and the general secretary of the society.

trary to what had been the case during the epidemic years 1901, 1902, and 1903, while the greatest multiplication of mosquitoes happened during the summer months. The rise and fall during the epidemics corresponded with the maximum and the minimum of the development of the mosquitoes.

PROSTITUTION. By J. L. Nascher, M. D., New York.

In Dr. Knopf's article, Some Thoughts on the Ætiology, Prophylaxis, and Treatment of the Social Ill, he omits several factors which, while not prominent in New York, are both predisposing and exciting causes of prostitution elsewhere.

In comparison with the great cities of Europe there is little prostitution in this city, and most of

that is a social evil and not a social "ill."

Dr. Knopf's distinction is, apparently, that it is an evil when the woman is knowingly and wilfully vicious, and it is an ill when the woman is unconsciously vicious through lack of proper education (including vicious surroundings) or lack of the inherent modesty of woman, or unwillingly vicious through physical defects, weak character, or want.

In this city there are very few women who become prostitutes on account of insufficient wages; indeed, few New York city girls become prostitutes unless brought up amid vicious surroundings. Most of the women found on the streets and in vile resorts are from smaller towns and villages, girls who could not resist importunate lovers, women deserted by their husbands, or who left their husbands, many who had been prostitutes elsewhere. Laxity on the part of the immigration authorities is responsible for the large number of foreign, notably French, prostitutes. These are sent to private houses of ill repute, all over the country, and after they have learnt the language they come to New York.

The stage is responsible for much prostitution here, and burlesque companies are hotbeds of vice. Of fourteen girls of a burlesque company stranded last December, four are now prostitutes. change from the farm to the stage, from the quiet humdrum existence of the country to the life and excitement of the city, produces a corresponding change in the girl who can stand it. A manager of one of these companies said: "After a country girl has stood the ordeal of two or three performances, she plunges into all the vices of the most hardened. Child labor is a negligible factor in this city as a cause of prostitution, and the numerous articles published on the subject of child labor in the South during the past three years have brought about better conditions everywhere. True, many girls become world wise and precocious in stores, shops, and factories, but that same wisdom saves them from fall when beset by temptation. Far more exposed are those who follow certain vocations which bring them in solitary and intimate contact with men. I might mention the manicurist, the cloak model, even the pretty typewriter who is alone in the office with her employer,

An investigation of the subject will probably

show that social and not economic conditions are responsible for most of the prostitution in New York. The predisposing causes are lack of proper education, vicious surroundings, and occasionally an inherent vicious disposition. The exciting causes in the vicious or "evil" are, the desire for pleasure or the gratification of erotic desires. In the "ill," the desertion of a lover or husband is the most frequent cause. Shame or pique is often followed by an abandon from which there is no recall.

How do conditions here compare with those abroad? Statistics in Scotland a few years ago showed that in eight counties from twelve to sixteen per cent. of births were illegitimate. The causes for this lack of chastity are intemperance and poverty. I had occasion to see these conditions while visiting the wynds and closes of Edinburgh two years ago. There were whole families occupying single rooms, families occupying adjoining rooms separated by a sheet, children drinking liquor in a public house (liquor store); a girl about sixteen years old so scantily attired that parts of her body were exposed, drunk; another one, no older and apparently pregnant, drinking with several other women on a street corner. The use of alcohol from childhood dulls the moral sensibilities, and the women do not resist their lovers' embraces. But outside of the seaports, Glasgow and Leith, etc., there is little prostitution in Scotland. (I speak here of professional prostitutes.)

In London there are three districts in which this class congregates. Near the docks are the old, haggard wretches; in Leicester Square are the French and Belgian importations, with a few English girls, the district at night being like the "Tenderloin" in New York. About the Elephant and Castle section were many women driven to their calling through want. Here economic conditions

were responsible for the social ill.

An attractive girl, about eighteen years old, earned ten shillings a week, and was obliged to contribute twelve shillings toward the household expenses. She went out Saturday nights and would make a couple of half crowns, getting as much in an hour as she earned in three days. She would not do this every day, as she was, she said, a respectable working girl. Her parents knew what her wages were, but never asked her where she got the rest. She told me lots of working girls were obliged to do the same as she did. While the curse of drink is responsible for much of the poverty in the British capital, the economic conditions are responsible for prostitution.

The low moral tone prevalent in Paris can be ascribed to two causes. The constant use of alcohol in the form of wine, from infancy, blunts the moral sense and dulls or destroys the instinctive female modesty. Pornographs, as readily accessible to the young as good novels are here, inflame the mind, stimulate the imagination, and arouse erotic desires. Alcohol and immoral literature, pictures and conversation form the predisposing causes. The government is responsible for the other. It licenses the houses of ill fame and the prostitutes, thereby giving them a recognized standing with certain rights. It takes away the stigma which attaches to prostitution, removing one of the most potent restraining influences upon women. The

demoralizing effect of legalized prostitution, as seen in Paris, is the best argument against state control or any other measure by which this vice may

be legalized.

Dr. Knopf evidently does not believe in the existence of born prostitutes. The daughter of a former school teacher in this city during early childhood evinced a fondness for playing with the genitals of her pets. Later she evinced the same tendency toward boys. She was repeatedly punished for this and for masturbation before she was ten years old. She left home shortly after puberty, and was found in a house of ill fame. The mother confessed that she had similar tendencies during her own childhood. In Paris I saw a similar precocious child who accompanied her mother, a prostitute, to a dive.

In Vienna most of the women of this class are either Hungarians or Viennese. The former are reared for the purpose and are inmates of houses. The latter, who secure patrons on the streets, in the parks, or cafés, take up this life to obtain the pleasures of the table, the bed, and the ball room. few are driven to it through want. Modesty and morality are not regarded as highly there as here, and a fallen woman can rehabilitate herself. The father of an illegitimate child must support the mother and child, and if unmarried cannot marry so long as she remains single and faithful to him. This feature saves many girls who under similar circumstances here would become prostitutes. Vienna, as in Paris, it is an "evil" and not an "ill." The women take up the vocation, knowing its immoral nature, yet willing to bear the stigma and risk the dangers for the pleasures to be derived.

In considering ætiological factors we must consider not only social and economic conditions and physical defects, but also racial traits, national conceptions of morality, the tendencies of vocations, the effect of alcohol as a factor, the educational facilities by which girls can learn the dangers of

prostitution.

Dr. Knopf suggests three methods for treating the social ill—segregation, shelter for those willing to reform, and treatment of venereal diseases. The last has really no bearing upon the subject of suppression or repression of prostitution. The social evil would exist if there were no such diseases as gonorrhoea and syphilis, and the existence of these diseases alone brings the subject, which belongs to the realm of the sociologist, under the physician's notice. There are several shelters which a fallen woman willing to reform can go to. But few go voluntarily, fewer are reformed, and very few stay reformed. The girl who has been able to make five or ten dollars a night by prostitution will not long remain in a situation where she can earn no more in a week

Segregation is neither curative nor preventive. The women congregate in districts where they are most likely to find the men who seek them. The visitor stopping at a Tenderloin hotel finds the women near his hotel, while the seaman will find his choice near the docks. No law and no force will bring the sailor to the Tenderloin in search of a woman who will dispense her favors, nor drive the up town women to the docks. Probably the most

efficacious method of dealing with the problem is to work on the causes of prostitution.

The treatment must be preventive, not curative. Whatever may have been the causes which drove the woman to prostitution, once a confirmed prostitute she does not want to be cured. There may be moments of shame, remorse, contrition, she may go to a home for fallen women, but sooner or later she will be obliged to decide between, on the one side, a boss, ten dollars a week, nine hours a day work, restraint, and fear of exposure; on the other, no master, five or ten dollars a night, no work, no restraint, pleasure, and abandon.

There are undoubtedly cases of girls who have reformed and remained reformed, but the few successes are probably due to the individual efforts of women who carefully select the cases, a woman taking one girl under her protection and restoring her

to respectability.

One of the most prolific causes of the social ill is the desertion of the pregnant girl by her faithless lover. Were there a law compelling him to support his child and its mother while she remains single and chaste, it would keep many of these unfortunates from going on the street. The present law against bastardy is ineffectual. I believe it has been decided that when a woman accepts money from a man who enjoyed her favors she is classed as a professional prostitute. The present of a dollar or two, "to buy candy with," should not be allowed as a defense in bastardy cases, to show that the girl accepted money for her favors, and is hence a prostitute, without rights before the law.

A woman known to lead an immoral life or suffering from a venereal disease should not be permitted to work in a store, shop, or factory where other women are employed. This should not, however, work to the detriment of the woman who is trying to lead a virtuous life after a life of shame.

There should be severe punishment, not a fine, but imprisonment, for the employer, foreman, or superior who assails an employee's virtue, though it be with her consent. This is a potent factor in the ætiology of prostitution among working girls.

Bad housing, emphasized as a factor in the causation of the social ill, is really of less importance in this connection than the racial traits of the dwellers. In the Ghetto, the most congested district in the world, containing many houses unfit for human habitation, prostitution among the Jewish girls is rare. The twenty-second chapter of Deuteronomy is impressed upon the children, boys and girls alike, as soon as they are able to understand its import. Here we see the practical results of religious education.

The debasing effect of alcohol upon the moral sense, as seen in Scotland and France and to a lesser extent in all wine and liquor drinking countries, is not presented to the public in a practical manner. Cut out the religious features and show the hygienic benefits of temperance or at least moderation. This duty should devolve upon medical societies and not upon church temperance and Father Mathew societies.

In this materialistic age men are more concerned about their bodies than about their souls, and the physician is better able to curb intemperance by sound advice than the minister who insists upon a

In the final analysis of the subject presented by Dr. Knopf we find the causes to be (1) improper education, (2) physical defects, (3) faulty social conditions, (4) economic conditions, (5) inherent viciousness.

The treatment indicated would be (1) proper religious and hygienic education, (2) medical treatment, (3) laws remedying the faults stringently enforced. The economic conditions adjust themselves or depend upon Providence for adjustment. Neither priest, physician, nor lawmaker can supply good crops and prosperity. As for the inherently vicious, they will remain in spite of all repressive or suppressive measures, and there are enough of this class to supply the demand of those who require their services.

A word about the pander. There is no law by which this contemptible fellow can be reached. Living on the earnings of the prostitute, driving her out to support him, a tyrant among women and a coward among men, he crushes by force any desire his victim may express to leave her vocation. Fear of his vengeance deters many of the fallen women from seeking an opportunity to reform. Yet he is above the law.

In asking that a more charitable view be taken of those who make efforts to return to respectability, let me recall the words of One who met a woman which was a sinner: "Thy sins are forgiven.
Thy faith hath saved thee."

HOW PLAGUE IS SPREADING IN VENEZUELA AND TRINIDAD.*

By James F. Donnelly, M. D., New York.

After examining carefully all probable sources I have come to the conclusion that it is shipping that has brought the plague to Venezuela and Trinidad.

It is my opinion that probably in the first instance the disease was brought from the Malabar Coast, India, either by immigrants, merchandise, rats, or other vermin, or by a chartered ship having been in the trade with India.

While we are not so interested in the question as to whence Venezuela received infection, we certainly are concerned in the controversy regarding

the infectious character of the plague.

In February of 1908, while on the Malabar Coast, the Parel Commission advanced the theory that plague is not infectious in the ordinary sense of the word, and that no disinfection or isolation of plague patients is necessary. The Public Health Department received the announcement of this decision with coldness, as it was pointed out that hitherto it had been firmly believed that the spread of plague could only be prevented by the segregation of patients, avoidance of contact with them, and thorough di intection, and that the balance of testimony was in favor of the efficacy of these precautions.

I prefer to be on the safe side, destroying all germs as a preventive measure until this point is more thoroughly investigated; and think the wiser

part for the United States is to take no chances, relax no precautions at any of her seaports until our knowledge of the nature of the plague is greatly increased.

Life is too valuable to be risked in support of a theory, and it will be generally admitted that the removal of any means tending to safeguard it should be undertaken only after the fullest and most care-

ful consideration.

The quarantine imposed by President Castro against La Guayra, which was not very effective, has been removed; and people are now free to go from La Guayra to any part of the Republic, carrying the plague with them; and now that we are in the summer months the disease will spread all over Venezuela unless some good foreign country comes to the rescue, as nothing is being done now to check it by the Venezuelan government.

However, the United States Sanitary Department on the Canal Zone is taking extraordinary measures to prevent the introduction and spread of bubonic plague in the zone by the extermination of rats, and other vermin, and I do not think the United States should be greatly alarmed by the presence of plague in South American ports, for energetic measures have been enforced under the direction of the U. S. Public Health and Marine Hospital Service and Dr. Doty, of the port of New York.

556 FIFTH AVENUE.

Our Readers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXVI.—How do you treat acute articular rheumatism?

(Closed July 15, 1908.)

LXXVII.—How do you treat varicose ulcer? (Answers

due not later than August 15, 1908.)

LXXVIII.—How do you treat acute coryza? (Answers due not later than September 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not requires) that the answers be short; if practicable, no one answer to contain more than six hundred

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

All papers contributed become the property of the Jounnal.

The prize of \$25 for the best essay submitted in answer to question LXXV has been accurated to Dr. P. A. Smithe, of Enid, Oklahoma, whose article appeared on page 166.

PRIZE QUESTION LXXV.

THE TREATMENT OF CHOLFRA INFANTUM. (Concluded from page 216.)

Dr. L. F. MacKen ic, of Wellileet, Mass., terres:

To properly treat this disease we must bear in mind that it is an acute intoxication occurring in hot weather and affecting not only the stomach and intestines but the system in general. That artificially fed infants are more liable to it than those who are breast fed, and, that any derangement of the alimentary canal is a powerful predisposing factor; that improper food, impure air, overcrowding, and had hygienic conditions are its forerunners; that the depressant effect of the toxines is chiefly exerted on the heart, nerve centres, and vasomotor nerves of the intestine; and that, in consequence of the latter, the intestinal capillaries are dilated, permitting a great outpouring of serum into the bowel, resulting in rapid loss of body fluid.

The treatment may therefore be considered under two heads: 1. Prophylactic. 2. Management of the

attack.

I. Prophylasis.—Very briefly this consists of an abundance of fresh air, pure food, in quantity, quality, and character suited to the age and condition of the infant, and attention to the sanitary condition of its surroundings. Bathing twice daily, oftener on hot days, with cool water, attention to excoriations around the buttocks, and immediate removal of soiled diapers or clothing are necessary. Garments should be light, loose fitting, and of some woolen material, and an abdominal binder worn. Weaning in hot weather is to be forbidden, and any derangement of the bowels, however slight, promptly attended to.

2. Management of the attack.—In so acute and rapidly progressive an affection as this remedial measures, to be effective, must be immediate and energetic, as the tendency is to a fatal termination

in spite of our best efforts.

The indications for treatment are: I. Control the vomiting and diarrhoea; 2, supply fluid to take the place of that lost; 3, combat the depressant effect of the toxines; 4, control fever and relieve other

symptoms present.

I. Stop all food for twenty-four hours and clear the stomach and bowel of offending material. There is no time to wait for drugs to do this, even if retained; so at once wash the stomach with sterilized normal salt solution at 100° F., and flush the colon with a similar solution at 80° F. After this give calomel 2 to 5 grains, in divided doses, to clear the small intestine and in four to six hours again flush the colon. Counterirritation to the abdomen with a light mustard plaster or cloths wrung out of hot mustard water-two tablespoonfuls to the gallonshould be applied and covered with oil silk. Creosote or carbolic acid, one half minim to the drachm of lime water, by the mouth every two hours, have a sedative and antifermentative effect in the stomach. Bismuth subnitrate, 10 to 20 grs., with resorcin, 1/2 to I gr., or sodium salicylate, I to 2 grs., are useful for the same purpose. The bismuth has the advantage of soothing the bowel and checking diarrhœa. Dover's powder is a useful addition to this if the bowel has been cleared and no drowsiness or stupor is present. Opium in any form is contraindicated, till the bowel has been cleared. After the lapse of twenty-four hours albumen water, and rice or barley with raw beef juice may be given in small quantifies at frequent intervals and the quantity cautiously increased, at the same time lengthening the period between feeding

2. To supply fluid and allay thirst hypodermoclysis must be relied on. Eight ounces or more of sterile normal salt solution in divided doses are to be introduced, into the buttocks, abdominal wall, or back near the scapula, in each twelve hours under

strict aseptic precautions. Boiled water in small quantities or small pieces of cracked ice may be given frequently by the mouth and salt solution gently thrown into the colon, some of which will be absorbed.

3. To control restlessness, check peristalsis, after the bowel has been cleared, stimulate the vasomotor nerves of the intestine and regulate the heart and respiration. Morphine, atropine, alcohol, strychnine are the best drugs: Morphine sulphate, 1/100 gr., and atrophine sulphate, 1/800 gr., should be given hypodermically to a child of one year and repeated every hour till relief is obtained. Alcohol in the form of good brandy or whiskey is stimulating, sedative, and saves tissue waste in the process of combustion. They may be given hypodermically or by the mouth, and from one half to one ounce used in twenty-four hours. Strychnine sulphate, 1/150 gr., every four to six hours subcutaneously is a powerful stimulant and is best reserved till signs of collapse appear.

4. For fever employ cold applications to the head and cool sponging with water to which alcohol may be added. If the fever is high use the graduate bath for ten to thirty minutes reducing the temperature of the water to 80° F, and flush the colon with water at 70° to 80° F. Antipyretic drugs

should never be given.

When collapse comes on the temperature becomes subnormal and the extremities cold. Stimulation should be active and food if taken should be warmed. Measures to maintain body heat must be employed. Flush the colon with water at 110° F. and place the child in a hot mustard pack or, bath, using gentle friction at the same time. When removed from this wrap it in hot blankets and surround these with hot water bottles.

Throughout the attack the child should be kept in a large, cool, well ventilated room, and be disturbed as little as possible. To avoid unnecessary handling it should lie on a bed or pillow rather than

the nurse's lap.

If the infant be breast fed the interval between nursings is to be lengthened to four hours, and the time of nursing shortened. Thin gruels with a little raw beef juice and plenty of boiled water should be given to supply the deficiency in food and fluid.

If the child survives the stage of collapse and reaction sets in there is danger of a relapse or that a chronic diarrhoa will develop. Careful regulation of the diet is therefore essential for some time, the quantity and quality being cautiously increased. Milk in any form should be prohibited till convalescence is well established and even then added, with great care, to the food, its proportion being gradually increased. Tonics, hygienic measures, and massage tend to hasten recovery. Laxatives should be avoided for a long time.

Dr. A. Griffin, of Valdosta, Ga., remarks:

Cholera infantum is a disease of such short duration, terminating either fatally, in recovery, or lapsing into a condition of ileocolitis, that the resources at our command for combating this most dreaded disease of infancy are very limited. Treatment must be begun early and directed to the individual case.

It is much easier, in my judgment, to do too much than too little. In private practice, and especially when the mother nurses the child, it is oftentimes difficult to make the family understand that the child is not being starved. Therefore, about the first essential, in the management of the case, is to get the family under control. The first thing I tell the family when called to a case of cholera infantum is that the diet (usually milk) is the cause of the child's illness. I usually ask the mother or nurse if the child does not vomit the milk, curdled, immediately after nursing. The answer almost invariably is that it does. I then tell them that as the milk is disagreeing with the child, which they can see as well as I can, it is absolutely necessary that we take it from the breast or bottle, whichever it may be, for at least twenty-four hours. I try to impress upon the family that there is no danger of the child "starving" in that length of time. With this preliminary preparation of the family there is usually no trouble in managing the diet of my patient, which I consider the most important part of the treatment. The first thing to do is to stop the milk until vomiting ceases. To quench the thirst and at the same time supply the patient with as much nourishment as it can retain, barley water or rice water, may be given when the stomach will retain them. A form of nourishment that I have found to answer as well, if not better than any other, and less often vomited is made by pouring boiling water over toasted bread and allowing to stand for an hour, and then give ice cold in small quantities frequently repeated. One teaspoonful is given, and if retained is repeated in thirty minutes, and if not retained is repeated in one hour. The quantity is increased as the stomach will tolerate it. No other nourishment is allowed for twenty-four house or longer, depending upon the condition of the patient. The milk diet should never be resumed so long as there is vomiting, nor for several hours afterward. Milk is also very sparingly given, so long as there is

The colon is irrigated three or four times in the twenty-four hours with a soft rubber catheter. A saline solution is used, and if there is high temperature, say 104° F. or 105° F., cold water is used, which serves a double purpose—that of cleansing the bowel and reducing the temperature.

If the case is one where there is great prostration with a normal or subnormal temperature, the water is used as hot as the child can well bear it.

Cold sponging serves a better purpose in reducing temperature than any other means in my hands. A temperature of 105° F, or above, that fails to yield to cold sponging, I use the ice pack with.

The cases with a blue surface and subnormal temperature are given the hot mustard bath and put in the hot pack.

As a stimulant, brandy with cracked ice is given when the stomach will tolerate it. If it is vomited, it is then given hypodermatically. Twenty minims to a child one year old, in desperate cases, can be given with safety every two hours. Strychnine in 1/500 gr. doses, hypodermically, every four hours, the given with safety every two hours and submertially that it is a submertial to the safety every four hours.

mically every three or four hours, acts well in my hands. The dose here given is for a child one year

The aim of the physician in the management of cholera infantum is to sustain the vital forces of his patient, eliminate the poisons, and prevent new ones from forming. The last essential is almost solely dependent upon the proper management of the diet.

Dr. John Purman, of Homestead, Pa., observes:

The treatment of cholera infantum is prophylactic, hygienic, dietetic, and medicinal. The true purpose of therapeutics is not only to restore the balance of health in the individual, but to reach much further and aim at perfection, for at the head of all forms of therapy stands preventive treatment. To prevent infection in cholera infantum requires absolute cleanliness of the child; more especially its food and care in its preparation. Milk should be sterilized and pasteurized. During the hot months pure cold water should be given freely to young children, the body protected by proper clothing, and as extreme changes from heat to cold open the way to infection, they should be avoided.

The hygiene of such patients demands careful consideration. They require the maximum of quiet, a uniform temperature, the utmost cleanliness, simplicity of diet, freedom from irritants of all sorts, and the least possible disturbance. The value of fresh air cannot be overestimated. For several years I have urged upon mothers in crowded quarters the value of taking children when ill with this and other gastrointestinal diseases to the country or parks, and keep them there, if only from early morning until late in the evening. These points are high, quiet, cool, and shady. Those who acted on this advice were delighted with the results. An open work hammock or light willow couch in the shade of a tree, with its refreshing breezes during the day, is far superior from a hygienic standpoint in the treatment of this disease than a dwelling with modern conveniences.

If the feeding of infants as now admitted is more important than any other agent in growth, development and repair, how much more essential is a correct understanding of the subject when the digestive organs are deranged or completely disabled by disease? Dietetic regulation is capable of overcoming a large group of disorders which when they persist pass into serious diseases. In cholera infantum neither nourishment nor water should be given (for from eight to twelve or even twenty-four hours) until the stomach ceases to be rebellious. When this point has been passed, water or ice should be given freely, but the diet should be of the easiest digestible character, with no requirement on the part of the normal functions for chemical changes; liquid strained farinaceous decoctions exclusively for the first acute stages; later the condition of the patient will determine the propriety of the administration of other articles of food, such as jellies without sugar, beef or mutton broths with farinaceous decoctions, egg albumoses, or alcoholic and

The medicinal indications are to clear out the gastrointestinal canal, check fermentation, and eliminate the toxines. Nature attempts to do this

by producing emesis and diarrhea. The most efficient remedy is calomel given in fractional doses (1/10 to 1/4 grain) every half hour for from six to ten or even twenty-four hours. It not only accomplishes all that the other remedies (magnesia, castor oil, or salts) do, but it is not so likely to be vomited, in fact it has a tendency to stay it. It stimulates the cells of the liver, the great compensatory organ of the abdominal viscera, to increased activity; equalizes the portal circulation by inviting the excess flow from the intestines to that organ, hence is more efficient in eliminating the toxines. Wash out the large intestines by high normal saline injections; this, at the same time, reduces temperature, replaces a certain amount of fluid in the blood and tissues, which have been lost through frequent vomiting and intestinal discharges. It flushes the kidneys, which are quite likely to become congested. If the temperature is high, tepid or cold water should be used, but in cases of extreme prostration, hot irrigations and hot baths (108° to 110° F.) are demanded. I doubt the propriety of hypodermoclysis, except in threatened collapse. It is seldom necessary to use the stomach tube; shock of it to the little patient is very great, but if vomiting persists for twentyfour hours, it may be necessary. If stimulants are demanded strychnine and brandy should be given and external heat applied. To check fermentation, bismuth subgallate (5 to 15 grains), combined with mercury with chalk (1/8 grain) has seemed to be When the stools are very green and excoriating, lactic acid (in 2 to 5 drops doses) diluted with water has been beneficial. In our effort to clear out the intestinal canal and check fermentation we at the same time aid in eliminating from the circulation the toxines that cause fever, convulsions, collapse, and death. After the intestinal tract has been thoroughly cleansed, if there is pain or loss of sleep, tenesmus, or cardiac weakness, I do not hesitate to administer a dose or two of opium, preferably morphine (1/50 to 1/30 grain) hypodermically. I would not, however, leave opiates in the hands of nurse or mother to be given in repeated doses. Astringents should be deferred until the acute stage has passed, as they might tend to prevent elimination.

The fact for the physician to keep in mind is that cholera infantum is a disease in which it is easy to do too little, but it is far easier to kill the patient in the hurry and haste of fighting the disease. When the acute symptoms have subsided, great care is still required, and both the mother and nurse must be impressed with the fact that diet is far more important than drugs. I have had no experience with serum or vaccine therapy in this disease, and space will not permit the consideration of the treatment of sequelæ.

Dr. Hans G. Baumgard, of New York, states:

Cholera infantum is mentioned along with summer diarrhœa, gastrointestinal catarrh, gastroenteritis, as a synonym of acute gastroenteric intoxication. It is but a severe type of gastroenteritis. Since the ætiology of the disease has been definitely settled as of bacterial origin, the treatment resolves itself into a, prophylactic; b, dietetic; c, medicinal and mechanical treatment.

A word more as to the ætiology, for one can only properly treat cholera infantum with a correct understanding of it. Milk is the key note; for no better culture medium can be imagined for the growth of bacteria. Add to this unhygienic surroundings and a continued minimum temperature of 60° F, and the bacteria flourish. Nature has showed us the way; the diarrhea is but the safety valve by means of which the body gets rid of the bacteria and the products of their growth. To stop the diarrhea is as unwise as to prevent the safety valve of an engine to properly functionate.

Taking up the division of treatment as mentioned. we first take up prophylaxis. Cleanliness is the great secret. Clean bottles, clean nipples, and, above all, clean, pure milk. The supply of pure milk to the poor, as conducted in New York, Boston, Rochester, etc., on a large scale has done wonders to lessen the number of victims. To be doubly sure, have all milk heated to 212° F. for one hour. Attend to all minor derangements of the stomach or bowels promptly. Avoid weaning in the summer months as much as possible. Breast feeding is a good guarantee, although breast fed infants are by no means exempt from the disease. Pay strict attention to the intervals of feeding and the quantity, for be the quality of the milk ever so good, too much will do harm. Rather cut down the amount of feeding and add boiled water to the diet list during the summer months.

b. Dietetic Treatment.-We have seen what a splendid culture medium milk is for the growth of bacteria, hence the first thing to do in a case of cholera infantum is to stop all milk. And I wish to be emphatic, because mothers will come and say, although explicit written instructions had been given: "O, doctor, I thought I could give the baby whey," or, "I only added a tablespoonful to the bar-ley gruel." There is no difference whether a teaspoonful be given or a pint, the crime is in giving milk. The diet should consist of barley water, this to be given in amounts according to the age of the infant. Oatmeal or rice gruel may be added. In older children vegetable soups may be given after the second or third day, also the volk of an egg beaten in with rice or oatmeal gruel. When the child's bowels move but once a day, and not more than the ordinary amount of mucus is present, the regular diet can be resumed very cautiously. Errors in this respect are sure to be followed by a

c. Medicinal and Mechanical Treatment.-The one drug that has given me the best satisfaction in these cases is calomel. The dose should be liberal, I grain twice daily for an infant of six months. This should be kept up until the diarrhœa subsides and then salol in 1/4, 1/2, or I grain doses twice daily will prove valuable as an intestinal antiseptic. Mechanically we get rid of the bacteria and their toxines by irrigations of the colon. A quart and a half of water, temperature 104° F., is injected into the colon three or four times daily, according to the severity of the case. Irrigation of the colon can be kept up for weeks without harm, gradually reducing to once daily. Vomiting, which is quite a frequent symptom, is treated by stomach washing, which can be performed readily, even in an infant a few

weeks old. The toxines thus resecreted by the stomach are effectually removed. Plain warm water, a rubber catheter, No. 16 French, with a funnel attached or connected with an irrigator, is all that is necessary. For stimulation no drugs are indicated, but weak tea sweetened with a little sugar will be found very effective as a stimulant. In desperate cases, where the tissues are like parchment and the system almost dried out from the removal of fluids, prompt hypodermoclysis of normal saline solution often saves a hopeless case.

Therapeutical Aotes.

Cardiospasm.—This is a name applied to a spasmodic contraction of the cardiac extremity of the stomach, and is, perhaps, a more frequently undiagnosticated condition than has been thought (Journal of the American Medical Association for July 11, 1908). Dr. Charles A. Wingerter, of Wheeling, W. Va., in the West Virginia Medical Journal, December, 1907, describes this condition. It occurs in "two forms: as a transitory paroxysmal affection lasting a few hours or even a couple of days, or as a chronic condition which may extend over a number of years." The acute cramp is short and painful, and is difficult to diagnosticate. The chronic type of cardiospasm is a more serious affection, as it interferes with the general nutrition of the patient and soon makes him an invalid. The author lays stress on the order of the symptoms as diagnostic, viz., early spasmodic pain, later regurgitation, and still later, retention of food a greater length of time after the meal before the regurgitation takes place. The pain comes on suddenly, and often radiates to the back or neck. In the intervals the patient is apparently well. After some weeks this spasm of the cardia causes a dilatation of the lower end of the œsophagus. From this time on the pain, distress, and regurgitation are more or less continuous, and emaciation begins. Soft food may still pass through the narrowed cardia, and if enough liquid and soft food is taken, the nutrition may keep fairly good and the regurgitation from the diverticulum may even become less frequent. The reaction of this regurgitated food is always alkaline, it is not acid, showing that it did not come from the stomach.

The cause of cardiospasm may be an ulceration, a new 'growth, hyperchlorhydria, or hyperæsthesia of the mucous membrane at the cardia. This, of course, may occur with neurasthenic and hysterical patients, but is probably often present when patients are considered neurasthenic and may be the cause of the neurasthenia. It occurs in both sexes and at any age. In the treatment of this condition, of course, if possible all local irritation must be removed, as gastritis or hyperchlorhydria. Some patients have the spasm of this muscle as a neurosis, especially when certain articles of food are eaten, particularly when by some previous experience they have found that such and such a food was followed by this udden pain and perhaps regurgitation, Such patients need aggestive treatment, as, if the patient can be made not to expect the attack, almost any food may be taken without harm. A spasm being present, morphine or codeine will stop it. Antipyrine has been recommended, and some patients do well with bromides. In its primary stage, no tangible cause being found, the patient should be treated as a neurotic.

Keratin Injection for Cirrhosis of the Liver.— Good results have been obtained by Zypkin in the treatment of cirrhosis of the liver by the hypodermic injection of a solution of keratin of the following composition:

The treatment is said to be useful in the treatment of sclerosis of other organs, such as the kidneys and heart, and a scientific explanation of the action of keratin on the constituents of the tissues is given.

—Wiener klinische Wochenschrift, 1907, No. 24;
Les nouveaux remèdes, July 8, 1908.

Paste Dentifrice.—The following is a simple combination that may be recommended where conditions warrant its use:

| \mathbf{R} | Potassium chlorate, | 3v | |
|--------------|--|----|---|
| | Medicinal soap basis (pure Castile soap),3ii | | |
| | Calcium carbonate, | | |
| | Oil of peppermint,gtt. | | |
| | Oil of cloves,gt. | 1V | 2 |
| 3.6 | Glycerin, enough to make a paste. | | |

Gargle for Quinsy.—According to Journal de médecine de Paris for June 27, 1908, Guisez uses the following gargle in the treatment of amygdalitis:

| \mathbf{R} | Carbolic acid, | xv; |
|--------------|----------------------|-------|
| | lycerin, | |
| | Tenthol,gr | . v; |
| | Cherry laurel water, | . 3v. |
| M. | | |

Sig.: A tablespoonful to be dissolved in a glassful of hot water and used as a gargle morning and evening.

Carron Oil for Alleviating the Pain of Acute Dermatitis is recommended by Sabouraud (Bulletin général de thérapeutique, June 15.1908), especially in cases where the skin affection has been produced by the free use of drugs like oil of turpentine and the bleaching compounds that are used in laundries.

Guaiacol in the Treatment of Pulmonary Tuberculosis.—The following methods of administering guanacol are cited in La Clinique for July 3d:

| Pills: |
|---|
| B Guaiacol, crystalline,gr xxxv |
| Tannin, |
| Extract of cinchona, |
| M. Ft. pil. xxiv. |
| Sig.: One to three pills every three hours. |
| Cachets: |
| B Guaiacol, crystalline, |
| Calcium triphosphate, |
| M. Ft. cachet xxiv. |
| Simon One attended to the Author |

- Solution in oil:

 B Guaiacol, crystalline, 5iiss;
 Codliver oil, Oil.
- Sig.: One tablespoonful two to four times a day.
 - Almond off, sterilized at 238 Page 1. La equal parts.
- Sig Give forty to titty drops in about three ounces of warm water as an enema daily.

NEW YORK, SATURDAY, AUGUST S. 16 S.

MINERS' NYSTAGMUS.

The president of the British Medical Association, Mr. Simeon Snell, F. R. C. S. Edin., made this the chief scientific topic touched upon in his address at the recent annual meeting, held in Sheffield. address appears in the British Medical Journal for August 1st, and advance sheets have kindly been sent to us. Mr. Snell, who is an ophthalmologist, regards nystagmus as preeminently a disease of coal miners--indeed, almost exclusively a disease of such workmen. He has had exceptional opportunities of studying it, for Sheffield, the field of his activities, is the centre of a great coal mining industry as well as the seat of famous manufactures in metals, notably the production of cutlery, which has made it conspicuous as the scene of development of another occupation disease, grinders' phthisis.

Mr. Snell believes that nystagmus as seen in coal miners is the product of a particular form of eye strain. Much of the work of the miners, it seems, requires them to crawl prostrate along low excavations and at the same time to keep constant watch of the roof of the particular excavation in which they are at work. Hence there is an almost constant strain on the muscles that roll the eyeballs upward, and nystagmus is apt to be the result. He does not go into the matter of the mechanism of the nervous genesis of nystagmus, as Gowers and others have done (see the next article). He thinks that the great liability to nystagmus on the part of miners might largely be done away with if provision could be made for enabling them to advance erect in their

work, but he fears that considerations of an economical character will continue to stand in the way of the adoption of such a protective measure.

Fire damp, as all the world knows, is a source of danger against which the miners must always be on guard. So special is the observation requisite to detecting the presence of this fatal gas in small amounts that in the English mines men known as "deputies" or "firemen" are depended upon to precede the miners at stated times, to detect the presence of fire damp, which they do by observing whether there is or is not a visual appearance known as a "cap" over the oil flame of the safety lamp. It appears that these "deputies" have often in their inspections failed to notice the warning "cap," and that a fatal explosion has occurred soon afterward. In that event it has occasionally happened that a "deputy" has been blamed and even punished for dereliction of duty, but Mr. Snell is inclined to believe that it is oftener on account of incapacity than by reason of carelessness that a "deputy" has failed to detect danger, for he finds that these employees themselves are prone to contract a degree of nystagmus which virtually precludes their perception of the "cap." The whole subject is certainly one of great practical interest to everybody concerned in coal mining.

THE MECHANISM OF NYSTAGMUS.

"The precise origin of nystagmus is still obscure" writes Sir William Gowers (Proceedings of the Royal Medical Society, June). That the oscillation of the eveballs which constitutes the symptom obviously depends on the alternate contractions of the opposite muscles has been grasped for some time, and the movement when slow and wide in range in the horizontal plane is seen to best advantage. How does this alternation come about? Sherrington's observations on automatic centres are of value in the interpretation of nystagmus. Thus, in his spinal animal, agonist and antagonist muscle groups pass into rapidly alternating automatic movements due in large part at least to the fact that the spinal centres contain a mechanism which, if unrestrained, automatically develops an alternate contraction of opposing muscles. These alternate contractions, Gowers says, seem to be essentially the same as those presented in well marked nystagmus. In the case of horizontal nystagmus, the external rectus moves the eye outward, and just before it reaches its full degree of contraction it suddenly ceases to contract, and at the same time its opponent, the internal rectus, contracts, and brings the eve back, a little more slowly. But, just before it reaches the middle position, this muscle in turn ceases to contract and the external rectus resumes its action, and so on, in continued automatic alternation.

This leads Gowers to ask if nystagmus is really a muscle reflex alternation between the antagonistic ocular muscles. Difficulties spring up, however. Neural spindles are a necessary part of the mechanism, and these, it has been thought, are absent in the ocular muscles. But Buzzard has recently disproved this. The spinal animal is an animal without a will, so to speak. But this does not seem to be the rule with disorders which show nystagmus, for here the lesions appear to be located in the midbrain, the pons, and the cerebellum and its connections. A midbrain ocular centre seems needed to combine and coordinate the various ocular movements so that binocular vision shall result, and Gowers believes that nystagmus depends on a disorder of such a midbrain centre, and that, although at first it may occur only when the voluntary impulse energizes the centre, the reciprocal action that is most disturbed may display an independence of the will and even opposition to it, so far as the direction of the quicker movement is concerned. The disturbance of the muscle reflex action, he suggests, is due to some insubordination of part of this midbrain centre.

PROPHYLAXIS IN SURGERY.

This was the title of the address in surgery delivered at the recent annual meeting of the British Medical Association by Mr. R. J. Pye-Smith, consulting surgeon to the Sheffield Royal Hospital. From a perusal of the advance proof slips which have kindly been furnished to us we infer that the address must have been most interesting to those who heard it read, chiefly because of the multiplicity of directions in which, as the author pointed out, surgery is really preventive in its objects, a variety that might not readily occur to one who had not made some special study of the subject. In a certain sense, of course, the aim of all surgery, as of all medicine, is prophylactic, but perhaps we are apt to overlook the immediate ills that it has for its object to prevent.

Surgical prophylaxis is directed, not only against the evils that are likely to happen if a certain procedure is not carried out, but also against such faults in the procedure itself as may render it vain or even destructive. It is in the direction last mentioned that asepticism, Lister's grand achievement, stands forth as the commanding feature. It is now little more than a platitude to remark that Listerism has opened new fields to surgery, yet it is only within the memory of many men who are now living that this new domain has been made over to the

surgeon, and most of us little realize the extent to which asepticism pervades the surgical work of the present time.

The great things to prevent in connection with a surgical operation, as Mr. Pye-Smith reminds us, are pain, shock, hæmorrhage, and septic infection. As regards pain, we have now so many and such various means of producing general or local anæsthesia that only an infinitesimal risk need be incurred in its induction and maintenance, though we still, as he remarks, need something better than morphine to allay the pain that so often follows recovery from the effects of the anæsthetic. To prevent or lessen shock, we must not carry to excess the fasting prescribed as a preliminary to anæsthetization, and we must take care that the subsequent exhausting vomiting be reduced to a minimum; we should administer the anæsthetic before the patient is brought into the operating room, so as to spare him the consternation which is almost inseparable from a sight that to him must be formidable; we should guard against all unnecessary chilling of his person, as when too large a surface of his body is exposed at once in procedures for disinfecting the parts surrounding the field of operation or too long a time is devoted to those processes or avoidable delay is suffered to occur for any other reason; and we should prevent unnecessary loss of blood. Hæmorrhage we can almost always guard against by the use of a sufficient number of hæmostatic clamps. Septic infection is generally to be prevented by strict adherence to the rules of Listerism. Though we cannot prevent a tumor, we can by judicious intervention often prevent its grave consequences, such as its continued growth, its pressure upon important parts, and its malignant degeneration, as in the case of fibromatous uterine growths. These are some of the ways in which surgery acts prophylactically, and many others were pointed out in the address.

THE PARASITIC AMŒBÆ.

The study of protozoan parasites by bacteriological methods is in every way desirable. For a long time this end seemed impossible of attainment, until Novy and MacNeal succeeded in cultivating Trypanosoma Lewisi, in 1903. In 1904 Musgrave and Clegg published the results of their attempts to cultivate Amaba coli, and in 1906 Leonard Rogers succeeded in demonstrating developmental forms of Leishmania Donovani in test tubes. These successes point the way to future developments in the line of the study of the parasitic protozoa in vitro.

In the February number of the Journal of Med-

ical Research there is an article by Dr. Ernest Linwood Walker on the parasitic amcebæ of the intestinal tracts of man and other animals, in which he reviews the question of the cultivation of these organisms on artificial media, their methods of reproduction, their nomenclature, and their distinctive characteristics. He finds that the essential requirements in the cultivation of amcebe on artificial media are a solid medium, which is slightly alkaline in reaction; the presence of living bacteria in the culture, on which the amcebæ may feed; and moisture, oxygen, and a temperature of from 20° to 25° C. (68° to 77° F.).

The author describes a most ingenious method of cultivating amœbæ on cover glasses. He spreads the agar medium on a clean cover glass and allows it to harden; he then plants the organisms and mounts the cover glass on a hanging drop slide sealed with vaseline. In this way the entire life history of the organisms may be watched, with a twelfth inch oil immersion lens if desired. The cover glass may be removed at any time during the development of the amœbæ, and the organisms may be fixed and stained. For the purpose of fixation, Zenker's fluid has given the best results, and for staining, Mallory's chloride of iron hæmatoxylin has been found most satisfactory.

By this method Dr. Walker has been able to elucidate many points in the life histories of the parasitic amœbæ. 'The schematic life history, as represented in a drawing, starts with an individual possessing amæboid movements. This individual divides into two individuals, probably by amitotic division, possibly by caryocinesis. One of these individuals may become encysted; the other may reproduce by the formation of spores. If the latter method occurs, the spores, which at first appear as fine refractive granules, gradually increase in size, and are extruded in from twenty-four to forty-eight hours. Each spore develops into an individual which is possessed of amœboid movements and goes through the same life cycle. From the encysted stage, which all amœbæ show at some time, the organisms become amœboid individuals.

Walker has thrown doubt on the accuracy of the observations of Schaudinn, who divided the parasitic amœbæ of man into Entamæba coli (nonpathogenic) and Entamæba histolytica (pathogenic). He believes that there is but one species, although he subsequently describes an organism which he calls Amæba hominis, which is different in its cultural characteristics from Amæba coli. He points out that the characters of the encysted stage of the parasites are of more value in determining species than the number of pseudopoda and the other characteristics of the amœboid stage.

From a study of forty-four cultures of parasitic amœbæ the author concludes that there are ten well defined species: Amæba coli, Amæba hominis, Amæba cobaye, Amæba musculi, Amæba ranæ, Amæba gallopavonis, Amæba muris, Amæba intestinalis, Amæba enterica, and Amæba fæcalis. The latter amæba has a very extended range of hosts. The question of pathogenic species can finally be solved, according to the author, only by the correlation of cultural, morphological, experimental, and anatomical studies.

PHYSICAL EXERTION BY CON-SUMPTIVES.

There is a widespread feeling in the profession to the effect that many a consumptive has seriously impaired his chances of recovery by injudicious horseback and other exercise. No doubt the feeling is well founded, but we must not suffer ourselves to fall into the belief that the "lunger" needs to become a lifelong loafer. What we should do, and what sanatorium supervision actually does, is to discriminate between the cases in which physical exertion is allowable or even advantageous and those in which, for a time at least, it is detrimental. This was clearly pointed out in the address in medicine delivered at the recent meeting of the British Medical Association by Dr. James Kingston Fowler. dean of the Faculty of Medicine of the University of London. The address, of which we have been favored with advance proof slips, dealt with many topics of great interest, chiefly those connected with the so called "vaccine" treatment of infectious diseases, and only incidentally with the question of work for consumptives, but that is such a vital matter for those who have to earn their living that we single it out for mention here.

Dr. Fowler tells us that a system of graduated labor devised by Dr. M. S. Paterson has for three years been in operation at the Frimley Sanatorium of the Brompton Hospital. In the course of two vears and a half the patients, to the number of 344. built a reservoir 108 feet long, fifty-eight feet wide, and thirteen and a half feet deep, capable of holding half a million gallons of water. In the excavation they had to remove 4,175 tons of earth and convey it to points of varying distance in baskets or barrows, mix and lav a thousand tons of concrete, and perform much other labor of a lighter character. He reports that at the present time 253 of these patients are earning their living, nine are not at work, eight have died, and seventy-four have failed to report. Speaking of the general run of the old patients, he says: "No one who has watched the change in the physical condition which in the course of six months or less occurs in these patients when

daily engaged in graduated labor, a change so great that at the end of their treatment they look more like navvies than consumptives, can imagine that a like effect can ever be produced by the administration of any drug."

It is largely with the aid of attention to the opsonic index, as we understand it, that this system of graduated labor has been carried out with such happy results. Dr. Fowler does not go into details with regard to this point, but refers us to Dr. Paterson's original exposition of the plan in a paper read before the Medical Society of London and published in the Lancet for January 25, 1908 (abstracted in our issue for February 15th, page 321). The accomplishment of such an enormous piece of work by sick men-sick with a disease which but a few years ago was almost universally regarded as hopeless-is certainly a striking proof of our advance in the management of pulmonary consumption, and it goes far to justify Dr. Fowler's contention that medicine has progressed as much as surgery in recent years.

Aews Items.

Plague in the Azores.—According to press dispatches, bubonic plague is spreading in Terceira Island. Twelve deaths were reported between July 27th and August 4th.

Personal.—Dr. Charles A. L. Reed, of Cincinnati, was recently made a Chevalier of the Legion of Honor by the Government of France. Dr. Reed is also a candidate for the Legion States Secret

The Pennsylvania State Board of Medical Examiners awarded certificates, which will allow the recipients to practice medicine in Pennsylvania, to 362 candidates out of a total of 395 who presented themselves for the examinations.

The Pennsylvania State Dental Examining Board has just granted license to practice dentistry to one hundred and seventy-six candidates after the annual examinations, held in Philadelphia and Pittsburgh. Thirty-six candidates failed to pass the examinations.

A New Hospital for Tarrytown, N. Y.—Mr. John D. Rockefeller has contributed to the building fund of the new Tarrytown Hospital the sum of \$25,000. The money is given on condition that the people of Tarrytown raise \$50,000 more.

A New Permanent Ward on the Boston Floating Hospital.—A new permanent ward with twenty beds was opened on the Boston Floating Hospital recently. When all these beds are occupied there will be one hundred and twenty permanent patients in the hospital.

A Tuberculosis Hospital in Rensselaer County, N. Y. Y. Y. An appropriation of \$25,000 has been made by the Renselaer County Board of Supervisors for the erection of a hospital for the treatment of advanced cases of tuberculosis. The institution will accommodate about sixty-five patients.

Contagious Diseases in Chicago.—During the week ending July 25, 1908, the following cases of transmissible diseases were reported to the Department of Health: Diphtheria, 55; scarlet fever, 40; measles, 38; typhoid fever, 21; whooping cough. 37; tuberculosis, 48; chickenpox, 1;

A Military Hot Springs Hospital in the Philippines.—
We are the The Wilton, in our that the military hospital at Camp Eldridge, Laguna, has been officially designated as a sanatorium for the special treatment of disnished by thermal springs.

Charitable Bequests.—By the will of Elizabeth Norris, the Home of the Merciful Savior for Crippled Children, of Philadelphia, receives \$10,000. The Home of the Merciful Savior is also mentioned as a contingent legatee. By the will of Angust Riedel, \$9,000 is bequeathed to the German Protestant Home for the Aged, at Lawndale, Pa.

The Des Moines Valley, Ia., Medical Association elected the following officers at its seventh annual meeting, which was held recently: President, Dr. L. A. Rogers, of Oskaloosa; first vice president, Dr. F. T. Stevens, of Mount Pleasant; second vice president, Dr. C. B. Powell, of Albia; secretary and treasurer, Dr. Fred Bowles, of

The Southwestern Medical Alumni Association, which is the alumni association of the medical department of the Southwestern University, Dallas, Tex., was organized recently, with the following officers: President, Dr. Sessler Hoss, of Muskogee, Okla.; vice president, Dr. W. B. Correll, Dallas, Tex.; secretary and treasurer, Dr. J. H. Block, of Dallas, Tex.

The Health of Michigan.—During the month of June, 1908, the following cases of communicable diseases were reported to the State Department of Health: Pneumonia, 84 cases; tuberculosis, 55 cases and 205 deaths; typhoid fever, 74 cases; diphtheria, 115 cases; meningitis, 46 cases and 52 deaths; whooping cough, 80 cases; scarlet fever, 162 cases; measles, 542 cases; smallpox, 124 cases.

The South Piedmont Medical Society held its sixth stated meeting in Lynchburg, Va., recently, and elected the following officers: President, Dr. H. B. Mohr, of Houston; first vice president, Dr. G. W. Cocke, of Danville; second vice president, Dr. W. L. Williams, of Brookneal; third vice president, Dr. J. A. Owen, of South Boston; treasurer, Dr. J. L. Kent, of Lynchburg. The next meeting will be held in November.

The Health of Pittsburgh.—During the week ending July 25, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 39 cases, 5 deaths; scarlet fever, 11 cases, 0 deaths; diphtheria, 8 cases, 0 deaths: measles, 40 cases, 7 deaths; whooping cough, 5 cases, 2 deaths; pulmonary tuberculosis, 22 cases, 10 deaths. The total deaths for the week numbered 163 in an estimated population of 565,000, corresponding to an annual death rate of 15,00 in 1,000 of population.

Hæmatological Tests on Arctic Explorers.—It is reported that the crew of the Peary Arctic steamer Roose-velt will be subjected to certain blood tests, with a view of obtaining some data regarding the effect of climatic conditions on the blood corpuscles. The tests, according to reports in the Halifax newspapers, are to be conducted by Dr. George M. Randall, of Lowell, Mass., who will go to Sydney for that purpose. Biological examinations will be made of the blood of various members of the crew before they sail, and further tests will be made on their return from the polar regions. Dr. Randall represents the American Hæmatological Association of Washington.

Civil Service Examinations to be Held in the Fall of gos.—Examinations under the rules of the United States Civil Service Commission will be held soon for the following positions: Physician in the Indian Service; Physician in the Isthmian Canal Service; Acting Assistant Surgeon in the Public Health and Marine Hospital Service; Surgeon in the Coast and Geodetic Survey; Trained Nurse in the Indian Service; Trained Nurse in the Isthmian Canal Service; and Trained Nurse in the Philippine Service. Application forms and information in regard to these examinations may be obtained by addressing the United States Civil Service Commission, Washington, D. C.

The Mortality of Baltimore.—During the week ending uses 1, 1908, there were reported to the Department of Health of Baltimore 200 deaths from all causes, as compared with 255 for the corresponding period in 1907. The annual death rate in 1,000 of population was 16,40 for the white population, 24.00 for the colored, and 17.61 for the total white and colored. The principal causes of death were: Typhoid fever, 6; whooping cough, 5; scarlet fever, 1; diphtheria, 2; consumption, 28; cancer, 9; organic heart disease, 10; pneumonia, 6; Bright's disease, 9; diarrhea and enteritis (infants), 38; diarrhea and enteritis (adults), 6; congenital debility, 18; old age, 1; suicides, 2; accidents, 9.

The Washington State Medical Association.—The annual meeting of this association will be held in Walka on September 7th, Sth. and oth Among those who have promised papers are Dr. J. C. Bloodgood, of Baltimore; Dr. J. R. Pennington, of Chicago; Dr. Paul Gronerud, of Chicago; Dr. H. D. Niles, of Salt Lake, Utah; and Dr. R. C. Coffey, of Portland, Ore. Every effort is being made to make this meeting one of the most successful in the history of the organization.

Two New Hospital Ships for the Navy.—It is reported that Surgeon General Rivey of the United States Navy will recommend that the next congress be requested to make an appropriation for the construction of two modern hospital ships, large enough to accommodate all the sick of any fleet to which they may be attached, and provide patients with the comforts and expert treatment to be had in a large hospital. The value of the hospital ship is being demonstrated by the Relief, which is accompanying the Atlantic battieship fleet on its voyage around the world.

Medical College Merger.—Announcement is made of the amalgamation of the Louisville Hospital and College of Medicine, the Kentucky School of Medicine, and the Medical Department of the University of Louisville, the new institution to be known as the Medical Department of the University of Louisville. The merging of these three medical schools, which has been agitated for several months, gives to Louisville one of the largest and best equipped medical schools in the South. A committee has been appointed to rearrange the faculty for the new institution.

Atlanta, Ga., Sanitary and Tuberculosis Society.—A

Atlanta, Ga., Sanitary and Tuberculosis Society.—A meeting of this society was held on the evening of July 31st. The new constitution was read, and will be adopted at the next meeting of the society. A committee, composed of Dr. J. L. Campbell, Dr. Claude Smith, and Dr. E. C. Thrash, was appointed to present to the senate resolutions on the need of a State sanatorium for the treatment of tuberculosis patients. Dr. Thrash read a paper entitled What the State Can Do to Prevent Tuberculosis, and Dr. Smith read a paper entitled What the Municipality Can Do to Prevent Tuberculosis.

A Medical Library in Nashville, Tenn.—A medical library, consisting of over four thousand volumes, will soon be opened to the physicians of Nashville and the surrounding country. Three thousand volumes were donated by the late Dr. Richard Douglas, and the other 1,400 volumes were obtained by Dr. M. M. Cullom. The meetings of the Nashville Academy of Medicine will hereafter be held in this library, which is in the Carnegie Library Building, and the weekly meetings of the scientific societies will also be held in the library, thus making it a medical centre for the city. Arrangements are being made for a series of popular lectures at the library during the winter. The committee in charge of the library work consists of Dr. W. D. Haggard, chairman, Dr. M. M. Cullom, Dr. R. E. Fort, and Dr. Holland M. Tigert.

Vital Statistics of New York.—During the week ending July 25, 1908, there were reported to the Department of Health 1,508 deaths from all causes, as compared with 1,507 for the preceding week, and 1,489 for the corresponding period in 1907. Of the total number of deaths 799 were in Manhattan, 146 in the Bronx, 481 in Brooklyn, 93 in Queens, and 49 in Richmond. The annual death rate in 1,000 of population was 18,50 for the whole city, as against a death rate of 22.05 for the corresponding period in 1907. The death rates for the five boroughs were as follows: Manhattan, 18,18; the Bronx, 23,25; Brooklyn, 16,81; Queens, 20,86; Richmond, 33,33. The total number of deaths of children under five years of age was 730, of which 424 were due to diarrhoad diseases. There were 2,630 births.

The Playground Association of America will hold its second annual congress in New York during the week of September 7th. President Roosevelt is honorary president and Dr. Luther Halsey Gulick, director of physical culture in the New York public schools, is president of the association. Mayor McClellan has been appointed honorary president of the congress, and invitations have been issued to the mayors of all the larger cities of the United States. The meetings will be held in the American Museum of Natural History. A great harvest festival will be held in Central Park, similar to the play festival held in Chicago in

1607, which will serve to demonstrate the value of the work and the interest taken in it. The programme will include addresses by Governor Hughes, Mr. Jacob Riis, Superintendent Maxwell, Mr. Joseph Lee. of Boston, and Dr. Woods Hutchingon.

The Mortality of Chicago.—During the week ending July 25, 1908, there were reported to the Department of Health 513 deaths from all causes, as compared with 526 for the preceding week and 548 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.35, as against 12.66 for the preceding week. Of the total number of deaths, 126 were due to diarrhoad diseases, of which eighty-six per cent. were of children under two years of age. The principal causes of death were: Apoplexy, 5; Bright's disease, 39; bronchitis, 5; cancer, 26; consumption. 49; convulsions, 5; diphtheria, 6; heart diseases, 34; intestinal diseases, acute, 126; measles, 2; nervous diseases, 24; pneumonia, 21; scarlet fever, 2; suicide, 7; sunstroke, 1; tetanns, 3; typholif fever, 5; violence (other than suicide), 42; whooping cough, 2; all other causes, 109.

Assembly of Kentucky recently made an appropriation for the purpose of encouraging the establishment and maintenance by private contributions of sanatoria for the care and treatment of the tuberculous. The bill provides, we learn from Charities and the Commons, that any sanatorium established by private contributions, which is not to be operated for profit, shall be entitled to receive annually from the State a sum equal to twenty per cent. of the amount involved in establishing and equipping it. It is further provided that no sanatorium shall receive in any one year an amount of money in excess of \$350 a year for each bed maintained, and that it shall not be entitled to receive aid unless it is actually established, is receiving and caring for patients, and has been in actual operation for a period of six months. The General Assembly passed another bill authorizing the establishment of a State sanatorium for consumptives to be maintained wholly by the State, but this measure was vetoed by the governor, on the ground of economy.

Philadelphia Bureau of Health Statistics.-During the month of June, 1908, in the Division of Medical Inspection, 1,871 inspections were made, exclusive of schools; 980 funigations were ordered; 30 cases were referred for special diagnosis; 5.190 visits were made to schools; 317 children were excluded from school; 141 cultures were taken; 100 injections of antitoxine were given; and 213 persons were vaccinated. In the Division of Vital Statistics 1,748 deaths, 2,954 births, and 1,180 marriages were recorded. In the Division of Milk Inspection 10,251 inspections were made of 238,241 quarts of milk, of which 234 quarts were condemned. Five specimens were examined chemically, and 1,258 were examined microscopically. In the Division of Meat and Cattle Inspection 2,829 inspections were made; 52 were found unsanitary; 281 pieces of dressed meat were condemned; 984 postmortem examinations were made; and 200 carcasses were condemned. In the Division of Disinfection 245 fumigations were done for scarlet fever, 287 for diphtheria. 53 for typhoid fever. 250 for tuberculosis, and 149 for miscellaneous diseases. Thirteen schools were fumigated. In the Bacteriological Laboratory 800 cultures were examined for the presence of bacillus diphtheriæ; 288 specimens of blood were examined for the serum diagnosis of typhoid fever; 1,258 specimens of milk were exemined; 150 specimens of sputum were examined; and 2,372,500 units of antitoxine were distributed.

Tuberculosis Exhibits at County Fairs .- A novel feature in the modern crusade against tuberculosis will be the holding of tuberculosis exhibits at the various county fairs throughout the State of New York. The State Charities Aid Association of New York is actively engaged in the preparation of six exhibits, which are soon to be started on tours through the State to be exhibited at thirty-six different county fairs. In addition to the pictures, literature words, see here photographs will be averaged. erature, models, etc., large phonographs will be employed having special records which will give much information on the subject of the cause and prevention of tuberculosis Each exhibit will be in charge of trained experts prepared to give any information desired by the public. Every phase of the disease will be dealt with in a thoroughly scientific manner, and at the same time the subject will be presented with a vividness that will awaken interest. In the State of New York there were last year 14,406 deaths from tuberculosis, and it is said that the disease is almost as preva lent, in proportion to the population, in the small towns and rural districts of the State as in the large cities. It is the purpose of these traveling exhibits to arouse the people to a realization of the extent of tuberculosis in the State and to show them how it may be cured if taken in time and how it may be prevented.

The Health of Philadelphia.—During the week ending July 25, 1908, the following cases of transmissible diseases were reported to the Burcau of Health: Malarial fever, I case, o deaths; typhoid fever, 44 cases, 4 deaths; scarlet fever, 19 cases, 4 deaths; chickenpox, 6 cases, o deaths; diphtheria, 46 cases, 6 deaths; cerebrospinal meningitis, case, 0 deaths; measles, 61 cases, 2 deaths; whooping cough, 46 cases, 11 deaths; pulmonary tuberculosis, 90 cases, 58 deaths; pneumonia, 22 cases, 19 deaths; erysipelas, 2 cases, I death; puerperal fever, 3 cases, 1 death; ryspletas, 2 cases, 0 deaths; cancer, 20 cases, 20 deaths; mumps, 5 cases, 0 deaths; mumps, 5 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 5; diarrhæa and enteritis, under two years of age. 87; tetanus, 1; dysentery, 4; cholera morbus, 2. The total deaths numbered 502 in a population of 1.532.738, corresponding to an annual mortality of 17.00 in 1.000 of population. The total infant mortality of 17.00 in 1.000 of population. The total infant mortality was 170; under one year of age, 139; between one and two years of age, 31. There were 43 still births, 20 males and 14 females. The total precipitation was 3.06 inches. The thermometer registered over 80° every day, and on hve days it was above 85°. There were 6 deaths from heat and sunstroke, 5 adults and 1 minor.

The Irish Women's Health Association was recently organized by the Countess of Aberdeen. As its name implies, it is intended to improve the physical conditions of the people by local organizations which are being formed in every town and village in Ireland. These organizations are composed of public spirited women of all classes, who are willing to devote some of their time to practical work of Ireland, provide nourishing food for the children, teach habits of cleanliness of person, clothing and habitations; teach the necessity of proper ventilation and the advantages of fresh air and frequent bathing; to instruct housewives and young women how to prepare food so as to secure the greatest degree of nourishment; to provide for in the markets; to prevent and punish the sale of impure or tainted fish, meat, milk, and other supplies; to have all milk inspected; to have all bakeries inspected; to secure the enforcement of the sanitary laws; to establish dispenwhere it is needed, and to do various other things for the physical welfare of the community. Lady Aberdeen is at present devoting her attention to educating the people on the question of tuberculosis. Tuberculosis exhibits have been held in more than sixty towns and villages, and the lectures which accompanied them were listened to by about one sixth of the entire population of Ireland. To aid in the campaign against tuberculosis a bill has been intro-duced into parliament providing for the establishment of eparate hospitals for the treatment of tuberculosis patients. A general supervision over the milk trade is exercised by the officials, and all physicians are required under a heavy

The Occurrence of Infantile Paralysis in Massachusetts

in 1907, By Robert W. Lovett.
Osteosarcoma of the Knee Joint,
By Edville Gerhardt Abbott and Thomas Jayne

The Abuse of Alcohol in the Treatment of Children's Diseases, By Charles W. Townsend, A Modification of the Drigalski-Conradi Litmus Lactose

Agar, for the Isolation of Bacillus Typhosus, By DONALD GREGG. 1. The Occurrence of Infantile Paralysis in

Massachusetts in 1907.—Lovett says that the evi-

dence as to the actiology of the disease may be summed up as follows: The sudden febrile onset and the character of the onset suggest infection, and there is a general impression that the disease is infectious; but the case is not proved by positive bacteriological data, so far collected, and most bacteriological examinations are negative. But in this case negative evidence does not disprove the theory of infection, for the organism present, if one exists, may liberate a toxine and disappear. The seasonal occurrence, the age of the children selected most commonly, and the frequent association of intestinal disturbance with the onset suggest some intestinal infection as the possible source of the disturbance. It must be remembered that the disease follows the curve of summer diarrhoea as to age and season, and follows the curve of cerebrospinal meningitis as to neither. From the evidence at our disposal, it seems reasonable to suspect that some bacillus, probably an anaerobic one, reaches the intestines in milk and there liberates a toxine which is absorbed and carried to the spinal cells by the blood current. Hence, the findings in the cerebrospinal fluid withdrawn by lumbar puncture are negative in most cases. But it cannot be regarded as certain that infantile paralysis is always caused by the same organism, nor even that it is a pathological entity. It may be simply the clinical expression of the reaction of the spinal cord to one of several causes, of which infection may well be one. A similar pathological condition has been seen to arise from lead poisoning from the experimental injection of bacteria in rabbits and from the injectine of toxine in guinea pigs. Allowance must also be made for the possible influence of traumatism, dampness, overfatigue, the exanthemata, and foci of pvogenic infection as possi-

ble causes of infantile paralysis, or a disease indis-

tinguishable from it. At present we must observe and study and collect material, remembering that

we may be dealing (1) with a specific infectious

disease; (2) with an infection due to one of several organisms, or (3) with a disease of more than one

origin, not always necessarily infectious. As to

contagion, the data contained are not sufficient to establish this characteristic, although the distribu-

tion of the disease, its spread from foci, the involve-

ment of contiguous towns, the spread along lines of

most frequent travel, and the very suggestive histories given may well warrant us in suspecting it and collecting further data, and no harm could arise from the isolation of such cases from other chil-

dren during the acute attack.

Osteosarcoma of the Knee Joint.-Abbott and Burrage, from their experience, think that a radical measure, such as an amputation, for the central variety of sarcoma of the knee joint, is advised for the following reasons: Early and high amputation give the largest percentage of recoveries without recurrence. Treatment by the use of toxines, which seems to be a useful adjunct, but alone, according to present statistics, gives only fifteen per cent. of cures in all varieties, cannot be entirely depended upon. Immediate death following operation seldom occurs if the previous condition of the patient is fair. Resection is of doubtful benefit, and, in cases where there is so much at stake, should not be attempted.

The Association of Age and Incipient Cataract with
Normal Pathological Blood Pressure. A Study of

these Conditions in Four Hundred Men above Sixty Years of Age, By D. W. Greene.

Middle Ear Sclerosis, or Atrophic Middle Ear Catarrh.—Bryant remarks that treatment should be directed to the correction of the systemic primary cause of the disturbed tympanic blood sup-Most important are general hygiene and systemic tonics, rest, and correcting any local cause of the general nervous disturbance. Also to the nasopharynx in order to remove the causes of disturbed tympanic blood supply; the nasopharynx must be put in as perfect physiological condition as possible. Furthermore, to the tympanic or tubal cause of altered tympanic blood supply which must be improved by local medical and surgical means; the tube must have its function completely restored; external mechanical obstructions to its action must be removed and astringents applied to the lining membrane. It should be directed to the substitution of normal cell elements for the pathological results of the sclerotic process; it is desirable to stimulate the tympanum violently in order to excite a reaction by which new blood vessels are formed and the circulation is restored, part of the sclerotic tissue absorbed, and the normal tissue stimulated. And finally to the restoration of the functions of the various parts of the sound conducting mechanism. To this end we have at our disposal the various forms of massage and inflation. These are all good if used with caution. The indications for their use are restoration of normal mobility to these parts. Counter indication is the hypermobility due to stretching of the connective tissue beyond its limit of elastic recovery.

3. Psychotherapy. — Barker remarks psychotherapy has had such a "yellow streak" in it that many medical men have refrained from utilizing to the full the good in it. This is one reason why it is desirable that conservative, scientifically trained men should work with it and let us know their experience concerning its advantages on the one hand and its limitations and dangers on the other. Its use should be preceded in every case by the making of an accurate diagnosis by our best methods. It is no cure all, but in certain cases it is indispensable. and with all patients it is a valuable supplement to other forms of therapy.

5. Chronic Pancreatitis.—Deaver states that chronic pancreatitis may be subdivided into the interlobular and the interacinar forms. For the purpose of the surgeon it is sufficient to state that the most frequent form is the interlobular, and that it is this form with which we have to deal in the pancreatitis complicating disease of the biliary passages. The interacinar form is due to systemic conditions not yet understood, and is therefore correspondingly unfavorable to direct or local attack. The ætiology of chronic pancreatitis is of the utmost importance. There is no doubt that its most frequent cause is some interference with the free discharge of the pancreatic secretion, either associated or unassociated with an ascending infection. As by far the most common cause of such obstruction is the lodgment of a gallstone in the ampulla of Vater, or other part of the common duct, the frequent association of the conditions is at once explained. The occurrence under such circumstances of a pancreatitis, either acute or chronic, is not inevitable, but it is very common. But gallstones are not the only indirect result. There may be an infection, as shown by the bile, congestion, and an inflammation of the gallbladder, or some cholecystitis, as evidenced in a shrunken and distorted gallbladder, or pericholecystic adhesions. Duct obstruction plus infection furnishes the most likely cause of chronic pancreatitis; either factor alone is sufficient to cause this condition. The rôle of infection alone is also demonstrable in those cases in which a chronic pancreatitis follows on a long standing gastroduodenal catarrh. Blocking of the pancreatic ducts by calculi in them or by new growths of the common duct or the ampulla of Vater may be mentioned as among the rarer causes of chronic pancreatitis. In considering the symptomatology we must remember that the symptoms are caused in three ways, and may thus be divided into three groups: 1. Those which depend on the local lesion, i. e., the local manifestations of disease in the upper abdomen. 2. Those which come as a result of the interference with pancreatic secretion, i. e., a form of indigestion. 3. Those depending on interference with the internal secretion of the pancreas-shown principally in the occurrence of diabetes and in the pancreatic reaction in the urine. The choice of operation in dealing with chronic pancreatitis resolves itself into a decision between simple drainage of the biliary ducts or a cholecystenterostomy. When gallstones are found in conjunction with pancreatic disease, or when the latter is found during a gallstone

operation, drainage is indicated by the biliary condition to be sufficient. Thus, if we have stones in the choledochus, a choledochostomy should be performed in the usual manner. The operation of cholecystostomy is to be preferred when we find a pancreatitis the result of a still active infection of the bile ducts or when the pancreatitis is discovered in its incipient or catarrhal stage. Cholecystenterostomy is indicated when the pancreatic condition is well advanced and we wish to procure permanent drainage. Moderate anæmia and glycosuria are not contraindications to operation in pancreatic cases, as both are often greatly benefited when the metabolism of the body is restored to its normal status. His results in chronic pancreatitis have been such as to encourage him to further operative work in this direction. The immediate mortality is still quite high, due in large part to the extremely weakened condition of the patients, the grave associated conditions, and especially the tendency in those patients in whom we find both jaundice and a pancreatic lesion, to uncontrollable

hæmorrhage. 6. Pancreatitis in Its Relation to Gallstone Disease.—Haggard writes that the acute type is so sudden and severe in its onset, attended with such agonizing pain and followed by such extreme prostration, that it has been denominated "the pancreatic drama." The pulse is rapid with rise of temperature. Vomiting occurs at once and is persistent. First, the stomach contents are regurgitated, and then the intestinal, simulating acute obstruction, although gas is passed. The lips are livid, the extremities cold, the entire body of a cyanotic leaden hue. Dyspnœa is often present, and constant splitting backache has been observed. The pain is excruciating, paroxysmal, and deep seated, and is uncontrollable with ordinary doses of morphine. Collapse is extreme. Tenderness is diffuse, and the whole picture is that of "the acute abdomen." There is some epigastric induration in the first twenty-four hours, but the consecutive distention soon obliterates it. There is no glycosuria. Erdman and Thayer found no sugar in five cases each. Patients die in collapse in forty-eight to seventy-two hours. This type occurs oftenest at about the age of fifty, in fleshy subjects addicted to alcohol. The laboratory examinations of the urine and fæces are so laborious and consume so much precious time in the acute cases and are really so inconclusive that it does not seem wise to delay exploration to have them made. The distinctive tissue change is fat necrosis. It results (when there is obstruction) from penetration, into the tissues adjacent, of pancreatic juice and certain ferments, which split the fat into its component fatty acid and glycerin. The latter is absorbed and the former unites with the lime salts to form yellowish white, nonelevated, opaque spots about the size of a millet seed that look like droplets of candle grease. Fat necrosis points as unerringly to the pancreas as jaundice does to the liver. There is also marked The colon and omentum are gorged In the omentum there have been observed clumps as large as sausages. In the subacute or suppurative form the onset is less sudden and severe. Chill, fever, and leucocytosis are present, and an epigastric tumor gradually develops. Although constipation is the rule, fatty stools and occasionally fragments of necrotic tissue may appear. A less violent course is pursued, sometimes ending in resolution. These cases frequently terminate in suppuration, which burrows in a bizarre way. Operation is not so immediately necessary in the subacute cases unless suppuration demands evacuation. Chronic pancreatitis occurs in individuals with previous painful epigastric attacks, which often declare their gallstone origin. There is midline tenderness, slight fulness, pain referred to the left side, to the kidney, and left scapular region. There is extreme loss of weight, which, with the pigmentation of the skin, frequently gives rise to the inference of malignant disease. Jaundice is com-monly present, and may exist for many months. Nearly all cases of so called catarrhal jaundice are in reality pancreatic catarrh or actual chronic pan-The intense irritation of the skin in jaundice is indicative of pancreatic and not biliary origin. The common duct is surrounded in the lower third of its course by the head of the pancreas in sixty-two per cent., which when swollen produces obstructive jaundice. In thirty-eight per cent. the duct runs behind the pancreas and, although it might be enlarged, no pressure jaundice results. The operative indication for the acute cases is unmistakable. Incision of the acutely inflamed pancreas with drainage often suffices. The peritonæum should also be drained when there is that peculiar beef broth serum present. If the patient's condition permits the complicating gallstones should be rapidly removed, and drainage instituted. In the chronic cases drainage of the bile passages, while indirect, is most effective. It is an anomalous illustration of a palliative operation being also a curative one. A thorough search with finger and probe after the removal of the obvious stones is essential to insure none being left. It is especially difficult to detect them in the pancreatic portion of the duct. The common duct is best drained temporarily with a catheter introduced up to the junction. Permanent drainage is to be established by cholecystenterostomy if there are no gallstones. The duo-denum, instead of the colon, is undoubtedly more desirable, as it delivers the bile into its natural channel, where it is physiologically needed.

 Surgical Technique Without the Use of Antiseptics;
 with Report of Forty-one Consecutive Successful
 Abdominal Operations, By William H. Dukeman.

 Epilepsy in Private Practice, Especially that from Reflex Causes,
 By Charles G. Polk.
- Tuberculosis in Connecticut, Especially in Rural Connecticut.-Maher remarks that tuberculosis was a disease of the Indians of Connecticut before the white man came. Human tuberculosis has occurred in all parts of rural Connecticut-high-

land and lowland and plain. There is considerable evidence to show that in rural Connecticut human tuberculosis occurs most frequently in badly drained districts, and in houses with damp cellars. The reports received do not support the view that in rural Connecticut cases of consumption occur frequently in close proximity to unsanitary barns or coops. While the preponderance of testimony is that in rural Connecticut only a minority of cases of consumption have been followed by other cases in the same house or the same family, the evidence in favor of the hypothesis of "consumption houses" and "consumptive families" is often very striking and is deserving of careful consideration. The density of the population of the counties of Connecticut bears no relation to the tuberculosis death rate of said counties. There has been a very marked decline in the tuberculosis death rate for the past fifty years. and this decline was as steep but not as regular before the discovery of the tubercle bacillus as it has been since.

Autochthonous Urethral Calculi.-Fowler describes the treatment thus: A small calculus in the penile urethra can sometimes be removed with the urethral forceps. In one such case, where the stone was freely movable behind a narrow point of the canal, he was able to fix the calculus by pressure on the urethra behind it, and remove it with the urethral forceps. Great care must be taken to avoid injury to the urethral wall, particularly in the presence of infection. In one such case reported gangrene and extensive sloughing of the urethra followed the removal of a small calculus impacted in the penile urethra. Attempts to crush the stone by pressure from without should never be made. If the stone cannot be readily removed by the forceps, it is safer to do an external perineal urethrotomy and remove the stone by displacing it backward. If this does not succeed one should then cut down on the stone, remove it, dilate the urethra, and suture, leaving the perineal wound open for drainage until the wound in the penile urethra has completely healed. For all large stones in the deeper urethra external perineal urethrotomy is the operation of choice. It will rarely be necessary to open the bladder above the pubes. In some cases of a small stone in the prostatic urethra it is possible to push it back into the bladder and remove it with a lithotrite.

5. Epilepsy. - Polk, in speaking treatment of epilepsy, observes that our present limited knowledge of the ease it must be largely experimental, physician studying each case and noting the results of the several courses of treatment. Passing to the hygienic treatment of the patient, it may be said that this is at least of equal importance with the medicinal. A course of treatment along comprehensive lines should be mapped out, and the patient be required to give reports as to his adherence to it. A copy of the following rules may be given him, they do not cover every case, but there can be no mistake in the observance of them: Have meals regularly, with the last meal of the day early and light. Do not eat until there is a sense of fulness. Do not eat peas, beans, veal, much meat, or cereals. A vegetable diet is the best. Fish and milk are permissible. Use as little salt in the food as possible, and forego tea and coffee. Do not eat much at one sitting. Keep the bowels free and the intestinal tract aseptic by the use of some antifermentative like salol or betanaphthol. Flush the colon frequently. Take warm salt baths, not remaining in the water sufficiently long to fatigue. Sleep with the head high, and keep the feet warm at all times, and especially at night. See that any defects in the eyes are corrected, and do not use the eyes a long time without resting. If glasses are worn, have the frames straightened at regular intervals. Take as much outdoor exercise as possible without fatiguing. Spinal douches and massage should be taken regularly. If seizures come early in the day take 15 grains of sodium bromide before retiring.

 Induced Hyperæmia (Bier's Treatment).— Waterhouse gives his experience with and conclusions regarding Bier's treatment by means of induced hyperæmia. He looks on inflammation as an attempt on the part of Nature to rid the tissues of the microbic invaders that attack any part of the body. Inflammation may almost be said to have, as its main function, that of excreting microbes. Bier's treatment has as its object the artificial stimulation of this excretory function by the production of a hyperæmia (venous or arterial), thus employing to the greatest available extent the antimicrobic action of the blood. The living tissues are aided in their struggle against microbic invasion, an increase in the volume of blood circulating through an inflamed part being, because of the antimicrobic action of the blood, a valued help to the issues in their contest with the invading bacteria. Bier's treatment should be entirely painless, and if pain is already present this should be mitigated, certainly after the treatment has been employed for a few minutes. Of the five cardinal signs of inflammation—heat, redness, swelling, pain, and impaired function-Bier's treatment increases the three former, and diminishes the two latter. The objects to be attained are: I. Arrest of the infective process or at least its mitigation. 2. Prevention of suppuration in many cases in which this is threatened. 3. Diminution of pain. 4. Avoidance of operative treatment in many cases, or, when this is not possible, the substitution of a less severe and less mutilating operation than would otherwise be necessary is permitted; thus, a few

small incisions are sufficient instead of many and extensive. 5. Saving of time owing to hastening the eliminating processes in cases in which suppuration and necrosis are unavoidable, as in carbuncle. 6. Increase in the antimicrobic action of the circulating blood owing chiefly to the greater quantity circulating in the diseased area. 7. Stimulation of process of repair, as shown very frequently by the success attending its use in cases of delayed union of fractures. Three methods are employed: I. Elastic constriction, the oldest and still the most frequently made use of. In general the bandage should be applied for nine hours on and three hours off in chronic cases in adults. After removal of the bandage the congested part is elevated and the area covered by the bandage sponged with seventy per cent. alcohol. Acute cases cannot stand too long an application. If suppuration has taken place prior to the application of the bandage, it is essential that vent be given to the pus. Bier's treatment is powerless to effect the absorption of pus already formed. Large, free incisions are not called for, however, and squeezing the abscess cavity should never be performed. In joint tuberculosis good results are attained by combining Bier's method with the use of a ten per cent, iodoform glycerin emulsion. 2. The second method of application of Bier's treatment is the partial vacuum or cupping glass method. This cannot be employed continuouslyone hour twice a day is usually sufficient. Suction causes a very marked hyperæmia, which is partly at first arterial, but in the main venous. It is used chiefly for affections of the trunk, but the results are far less striking than are observed in the extremities by the use of elastic constriction. 3. Of the third method of Bier—that of the induction of hyperæmia by means of hot air—the writer has had but little experience. In this method the part, naturally an extremity, is enclosed in a chamber heated artificially to 200° to 250° F. In conclusion, the writer cites twenty cases in which the treatment was employed with advantage.

2. Nasal Obstruction.-Spencer takes up the question of nasal obstruction under the following heads: 1. Adenoid vegetations. The writer prefers the removal of adenoids by means of forceps followed by the ring knife. Adenoids are produced by a persistent habit of mouth breathing, resulting usually from neglected and recurring catarrhal infection. 2. Congenital nasopharyngeal obstruction. Defective development of the base of the skull may cause a false appearance of adenoidism. Abnormally narrow posterior nares is another form of congenital obstruction. 3. Nasopharyngeal polypi (a) lymphadenomatous and cystic nasopharyngeal growths. Old adenoids tend to become ædematous and cystic. (b) Myxomatous nasopharyngeal polypus. These grow from some point around the posterior nares, and can be safely removed either with a snare or forceps. (c) Fibrous nasopharyngeal polypus. This grows from the fibrocartilaginous covering of the base of the skull, and may grow to a large size before being recognized. It is identified by its having a limited but fixed attachment to bone. It should be removed by doing preliminary laryngotomy and plugging the pharynx, all in dividing the soil palate and retracting each

half. The base of the tumor is outlined by the cautery and the tumor detached by raspatories. (d) Inoperable congenital tumors in connection with the hypophysical region of the skull, dermoid cysts, teratomata, etc. 4. Nasal polypi. Benign polypi are started by a local hypertrophy of the normal submucous tissue, by proliferation of the original tissue cells, accompanied by an increased vascularity. The earliest stage is commonly seen over the end of a turbinal bone, forming the sessile hypertrophy. When there is added the saturation and separation of the connective tissue fibres by serum, a mucous polypus forms. In the early stages simple treatment-washes, tannin, alcoholmay cause subsidence. Fibrous nasal polypi usually occur in boys before or soon after puberty, and if not attended to cause the so called "frog face." 5. Abnormalities of the nasal septum cause nasal obstruction, and treatment should be directed to the relief of that condition. Deviations and spurs of the septum are not otherwise important. 6. Acquired nasal obstruction is produced in particular by syphilis, and is most difficult to relieve.

2. Errors of Metabolism. — Garrod, in the third of his Croonian lectures, takes up the subject of cystinuria. The liability to the formation of calculi composed of cystin and to other urinary disorders such as cystitis, gives the study of cystinuria a practical as well as a theoretical importance. A distinct odor of sulphuretted hydrogen is given off from such urines when they decompose. The deposits of crystalline cystin which are thrown down are not very abundant, but may often be seen with the naked eye to consist of glancing crystals. der the microscope these appear as hexagonal plates, the edges of which usually show paired inequalities of length. Fresh crystals are deposited after the urine has been passed, especially on addition of acetic acid. The ready solubility of cystin in ammonia affords a means of identifying the crystals, which are insoluble in acetic acid. The urinary crystals which are most likely to be mistaken for the hexagons of cystin are the almost colorless plates of uric acid deposited from feebly pigmented urines. The cessation of deposits must not be taken to mean that a patient has ceased to excrete cystin, for the addition of acetic acid may cause their deposition. Even in acid urine cystin is by no means insoluble But there is reason to believe that the excretion of cystin may be actually suspended, at least for a time. Possibly the error of sulphur metabolism persists, although the form of its manifestation is changed, and in such cases some other interme-

diate product than cystin itself may come to excre-In the fæces of cystinurics no cystin can be The error of metabolism, of which cystinuria is a manifestation, is clearly a far more complex one than that which underlies alkaptonuria and far less uniform in character. Although the excretion of cystin in the urine is apparently a constant feature, and is that by which it has always hitherto been recognized, yet cystin is by no means the only protein fraction which is implicated, and in some cases other aminoacids or their derivatives are to be found in the urine. The commonest of these are the diamines cadaverin and putrescin. More rarely leucin and tyrosin are excreted unchanged. So that cases of cystinuria differ widely among themselves not only in the number of protein fractions which are implicated, but also in their behavior as regards the individual fractions. The cases can be classified along the following lines: 1. In some no diamines and no primary protein fractions other than cystin have been found in the urine. some the urine has contained cadaverin or putrescin, or both, in addition to cystin, but the excretion of diamines is apt to occur in an intermittent manner. 3. In a very few cases leucin or tyrosin or both have been excreted with or without diamines. 4. In one case cystin was present in the urine, but no diamine, leucin, or tyrosin. When diaminoacids were given by the mouth the corresponding diamines were ex-As regards the disturbance of sulphur metabolism in cystinuria it is certain that only a portion of the total cystin of the proteins broken down is excreted as such, and that the error is in no sense complete. Cystinurics always excrete neutral sulphur and sulphates other than that contained in the cystin. It is probable that the unchanged cystin is excreted at the expense of the sulphates rather than at that of the neutral sulphur. The question as to whether the excretion of cystin is influenced by the amount of protein in the diet is not as yet settled.

3. Opsonic Index in Pulmonary Tuberculosis. -Smith, Elder, Radcliffe, and Crossley have studied the opsonic index in cases of pulmonary tuberculosis, and find that they can classify the cases into three groups, as follows: I (Those showing extreme and rapid oscillations in opsonic power). In cases of this type it was thought that as even at rest the autoinoculations were so marked the results of tuberculin treatment would probably be unfavorable. 2 (Those with persistently high level indices). Injections of tuberculin were not given here, as it was considered it would not be possible to improve the patient's opsonic power and the risk of inducing a negative phase would have been incurred. 3 (Those with low indices). Injections of tuberculin were instituted in these cases and apparently with excellent results. The writers also found that the agglutinins and opsonins in pulmonary tuberculosis follow a similar course, but that the opsonic estimations are more delicate and record much slighter varia-

Blood Pressure in Neurasthenia.--Macnamara has studied the blood pressure in various neurasthenic states, and summarizes his conclusions as follows: 1. In many cases of neurasthenia there is an alteration of the level of the blood pressure from

the normal, the level being sometimes higher and sometimes lower than the normal. 2. Patients who show such alterations and who undergo certain sorts of treatment manifest, in some cases, at the end of a course of treatment a level of pressure different from that which existed before treatment began. If the pressure at the commencement be abnormally high it will probably descend, while if it be abnormally low it will probably ascend. 3. The number of patients whose blood pressure is different at the end of their course of treatment from that which it was before treatment began is greater among those without a family history of nervous instability than among those with such a history. 4. In a very large majority of cases the application of high frequency currents produces a lowering of blood pressure, while the static bath (+ charge) and massage produce a raising of pressure. The discharging of a patient charged with static electricity results as often in a rise as in a fall of blood pressure. application of the faradic current tends rather to lower than to raise the blood pressure, and the galvanic current cannot be said to effect much change in either direction. 5. It is difficult to institute treatment with any confidence that there will be at the end of the course such an alteration as might perhaps have been expected from a knowledge of the alteration that is likely to follow each application of the therapeutic agent employed, though we may look for a change of level, when the level was at the commencement abnormal, to one that is nearer the normal. 6. There is no evidence that the differences of variation of level before and after treatment which may sometimes be noted can be correlated with improvement in health.

By H. KNOPF. 10. Examination and Treatment Under Water in Gynæcology and Obstetrics,

11. Concerning the Provision of Hospitals and Infirmaries
By B. Laquer.

The Methods of Military Sanitation in 1906 and 1907. By G. SCHMIDT.

3. Glycosuria Experimentally Produced by Cauterization and the Formation of Eschars on the Inner Surface of the Intestine.-Eichler and Silbergleit allege to have shown by their experiments that injury to the mucous membrane of the duodenum produces glycosuria, with a constancy

and with an amount of excretion of sugar such as has never been described in connection with any analogous irritation, a fact which is of considerable

interest in experimental work.

4. Little's Disease and Luxation of the Hip.
-Wollenberg has collated the reported cases of Little's disease, which he has divided into two groups, those without and those with luxation or subluxation of the hip. He then reports four cases of Little's disease, the first a boy, four years of age, with double congenital flatfloot; the second a boy of three, with ulnar club hand; the third with coxa vara of high degree on the left side; the fourth with a supernumerary thumb on the right hand; the fifth with hydrocephalus. Finally he concludes that the cases of luxation of the hip in consequence of Little's disease show that the mechanical origin of a hip luxation is possible, the same as a mechanically produced paralytic luxation, and also that with this mechanically produced luxation similar changes may take place in the acetabulum as those observed in congenital luxation of the hip.

Torsion of the Pedicle of the Gallbladder. -Mühsam reports a case in which the diagnosis of empyema of the gallbladder was made from the symptoms produced by a torsion of its neck, and a laparotomy was performed. The patient made a good recovery. The only treatment in such a condition as that here described consists in extirpation of

the gallbladder.

9. Cure of Chronic Bronchitis by Respiratory Gymnastics.—Knopf says that all expectorants whose utility are unquestioned have more or less unpleasant after effects, and that the methodically practised deepening of the respiration is not only the most certain, but also the only entirely harmless expectorant.

II. Books for Hospitals .- Laquer urges the saying of Lichtenberg, "Books can make the reader neither bad nor good, but can make him worse or better," and that books for the reading of hospital patients or convalescents should be carefully se-

lected.

3. Metalymphæmic Cirrhosis of the Liver .--Mosse reports a case in which he ascribes as the

probable cause of the cirrhosis of the liver the injury to the cells of the parenchyma of the liver by the dead and dying lymphocytes produced by the treatment with x rays.

5. Landry's Paralysis.—Münzer alleges that with clinical unity this disease presents an anatomical dualism, one class showing the lesions of acute poliomyelitis, the other those of acute polyneuritis. He reports a case in which the anatomical changes of acute poliomyelitis were very marked.

7. Acute Yellow Atrophy of the Liver from Syphilis.—Bendig reports a case of this nature and also two cases of severe jaundice during the

secondary stage of acquired syphilis.

9. Paralysis of the External Rectus Associated with Purulent Otitis Media.-Peyser reports a case in which purulent otitis media followed an attack of scarlet fever in a twelve year old girl. A tumor appeared before the right ear, with slight swelling of the right upper lid and paralysis of the external rectus. The subperiosteal abscess was opened, and a thorough mastoid operation performed. The paralysis of the external rectus gradually improved. In another case, a boy eighteen years old, paresis of the left abduces appeared after a mastoid operation on the right ear. He also had marked choked discs in both eyes. These conditions disappeared without treatment.

10. Total Resection of the Sternum and Operative Cure of a Pulmonary Cavity, The Dermatotherapeutic Valuation of Static Electricity

According to Suchier (concluded), By J. Obituary of Dr. Gregor Schmitt of Würzburg. By JESIONEK.

1. Chondrotomy of the First Rib in Commencing Tuberculosis of the Apex.-Seidel considers this form of treatment suitable in all cases of tuberculous catarrh of the apex in adults and young people who have a demonstrable stenosis of the upper aperture; in all cases of tuberculous catarrh of the apex in older adults even when no marked stenosis of the upper aperture of the thorax can be recognized in case ossification of the cartilage of the first rib is met with and movement of the ring of the first ribs is difficult; in cases of tuberculous catarrh of the apex in adults in whom the thorax is comparatively well formed, when, in spite of internal treatment, complete disappearance of the catarrh cannot be brought about. Autopsies have shown that the ring of the first ribs may be so small as to cause compression of the tissues at the apex. Chondrotomy must be considered simply as one among

many means with which to combat this disease, it

does not take the place of the others.

2. Diagnostic Vaccinations with Tuberculin Free from Fat.—Leber and Steinharter, after an experience with 350 cases, recommend a tuberculin from which the fat has been removed for use for diagnostic purposes.

4. Oophorin .- Hirschberg recommends oophorin, a preparation of ovarian substance, to be given women at the climacteric age and also to younger women who are suffering from amenorrhœa.

6. Diseases of the Lachrymal Canal.—Enslin pleads for a greater extension of the benefits to be obtained from an extirpation of the lachrymal sac as the treatment for dacryocystitis.

10. Resection of the Sternum.—Siegel reports a case in which he resected the entire sternum from a woman, twenty-six years old, on account of tuberculosis and secured the repair of a cavity in the lung. The patient made a good recovery.

Intrapelvic (Subpelvic) versus Abdominal Method of Dealing with Mechanical Obstruction to Delivery in Cases of Confinement,
 The Indications for Cassarean Section, By B. C. Hirst.

Immediate versus Deferred Operation for Intraabdominal Hæmorrhage Due to Tubal Pregnancy.- Janvrin assumes that the question referred only to operative treatment. Practically every case of extrauterine pregnancy is at first tubal and in its early stage is unruptured. The author recalled the fact that he had advised, in 1886, for such cases abdominal section and removal of the unruptured tube with its contents as soon as the diagnosis could be made. The symptoms of ruptured tubal pregnancy are now so well known that diagnosis is not usually difficult. The author's preference is for abdominal section as soon as the rupture is determined, for the mother's life is in danger as soon as the hæmorrhage begins. fœtus and placenta being retained, become a source of danger as foreign bodies. The only excuse for delay in a condition of this character would be the

inability to obtain a competent surgeon. This, however, would not usually necessitate a delay of more than a few hours. If an operation is done at once, the danger from intestinal and other adhesions would also be obviated. If an operation is deferred, shock and loss of power for reaction are additional factors which must be considered.

5. The Time to Operate in Intraabdominal Hæmorrhage Due to Tubal Pregnancy.-Manton considers five conditions of this accident: 1. The fulminating cases, with excessive hæmorrhage from rupture of the tube or expulsion of the ovum from the ostium abdominale, with profound shock and collapse. 2. Those in which there are repeated attacks of pain, with faintness, vomiting, and shock, but without excessive bleeding, as in tubal abortion. 3. Those in which rupture has occurred and an hæmatocele has been walled off from the general peritoneal cavity. 4. Those in which the blood has been more or less absorbed, the products of conception and exudate remaining. 5. Those in which the products of conception have escaped from the tube and continue to develop. In determining the course to be pursued when hæmorrhage has occurred, rare judgment fortified by experience is essential. Accumulated experience demonstrates that if there is free blood in the peritoneal cavity the sooner an operation is undertaken the better the chances for rescuing the patient. The management of this condition demonstrates literally that "the man that wandereth out of the way of understanding shall remain in the congregation of the dead.

14. The Indications for Cæsarean Section .-Hirst says that women with a conjugata vera of eight centimetres can be delivered safely and easily during the last month of gestation who would require Cæsarean section or pubiotomy at term. The mortality of premature infants is little higher than those born at term in unobstructed labors. There need be no dread of Cæsarean section after hours of labor pains if the operative and aseptic technique is good. The author has performed seventy-seven Cæsarean sections, under many conditions of labor, with five deaths. His technique consists in cleansing the vulva and vagina thoroughly, packing the vagina with sterile gauze, covering the abdomen with a rubber dam, delivering the uterus from the abdominal cavity, and packing of the abdominal cavity with gauze. The uterus having been evacuated, its walls are united with four interrupted sutures of Pagenstecher's thread of the finest size. The myometrium is then united with a double tier suture of chromicized gut, and the peritonæum with a double laced suture of catgut. The uterus is then returned to the abdominal cavity, the toilet of the peritonæum made, and the abdominal wound closed. Such a technique makes Cæsarean section comparatively safe at any stage. If there is serious infection, with gangrene of the vulva or sloughing of the vagina, the Pono operation can be performed.

Arterial Structure and Arterial Function,

By WILLIAM RUSSELL. I. Blood and Mind .- Clouston, in the Harveian Oration, remarks that the relationship of the bloodvessels and the blood to mental disease has attracted much attention of late years in the United Kingdom and in Italy particularly. Dr. Rutherford M'Phail, in 1884, made a careful investigation into the condition of the blood in mental disease, and his conclusions are very important and definite in regard to the manner in which it is affected in the different forms of insanity. He found that in the patients who suffered from the acuter types of the disease and in the demented class, as well as in general paralysis, the blood was deficient in hæmoglobin and in the number of red and white corpuscles. In the patients who improved in mind, their blood also improved during their asylum residence, and when fully recovered it attained the normal standard. He also found that certain tonics, notably iron, quinine, and strychnine, had a marked effect in improving the quality of the blood. Anæmia he found to be present in a very considerable proportion of melancholics, and to remedy this is one of the first aims of the physician. There are certain cases also where delusional states arise as the result of certain heart diseases and of anæmia. All the great clinicists in psychiatry have directed attention to the condition of the blood in mental disease and have connected abnormal conditions of blood with the mental disturbances, but Dr. John Macpherson was the first to extend and definitize our views as to the great part which toxines and autointoxication play in the ætiology of certain insanities. Clouston believes that the relationship of blood and mind is not all on one side. His experience of mental disease would be a greatly mistaken one, he remarks, if it was not the case that the normally energizing mental cell has a marked effect on the quality of the blood and on the tone of the capillaries and arterioles for good. On the other hand, no one who has seen the pallor, the bad color of the skin, the sunken eye, and the unresistiveness against cold of the man depressed by bad news, and who has seen the same man a month after he has had good news and prosperity has come to him, without observing the mental effects on his blood of the restored cortical action. His blood has "thickened." and his cerebral capillaries and arterioles have resumed their normal tone through the stimulation of his mental cortex. There can be little doubt that general mental activity is stimulated by certain constituents of the blood, and that it is retarded by the existence of others. The consensus of opinion among brain workers tends towards the view that light animal foods, such as fish, milk, eggs, and fruits, are the diets on which they can do the best

I. The Climates Suitable for the Aged .-Weber asserts that the climatic management of old age demands much more careful consideration than does that of any other period of life, for the defects of old age are superadded to the requirements of constitution and morbid disposition. The conditions which are especially to be considered are the changes in the system of circulation, reduction in size and power of the muscular system, diminished acuteness in perception and transmission in the nervous system. In general, old age is characterized by diminished resisting power. The winter and early spring should therefore be spent in climates where there are warmth, sunshine, absence of high wind, mental exhilaration, pure air and water, good hygienic arrangements, and judicious medical advice. Among the desirable localities mentioned are Egypt, Algeria, the western and eastern Rivieras, Abbazia on the Adriatic, the Ionian Islands, Pau in southwest France, and some of the lower Alps. In the United Kingdom there are various desirable resorts in the southeast, south and southwest coasts of England and Ireland. Out of door living and pure air at all times are the great

2. Health Resorts and Climates for Children. -Carr observes that spas and health resorts play a small part in the treatment of disease in early life. Climate is, however, a matter of vital importance t the growing tissues of a child, with his tendency toward nutritional disease. A good climate is next in importance to proper and sufficient food. For children in ordinary health it is of practical importance, especially for those living in cities, to spend the vacation where it will give the best return in health. For such diseases as nephritis or tuberculosis the same climate which would benefit an adult would benefit a child. For chronic bronchitis the winter should be spent in a warm and moist climate, like the Canaries or Algiers. For children with heart disease a dry, bracing climate should be selected. For scrofulous children sea air is preferable, or the saline springs, or the sulphur waters. In the summer the country is to be preferred to the sea shore, and a farm house with good sanitary arrangements is infinitely better than a fashionable

hotel by the sea. 3. Change of Air in Young Adult Life and Early Middle Life.-Weber thinks change of air has cured many a disease, with or without a doctor's help. The most satisfactory results from such treatment come to brain workers from the beginning of adult life to middle life. The principal factors which produce the beneficial effect are more open air life, more muscular exercise, and mental factors. Open air life in a hilly country may be said to prevent cholelithiasis. The sedentary life in cities favors gastrointestinal troubles, circulatory troubles, liver disorders, mitral disease, and pulmonary emphysema. Open air exercise tends to remedy such conditions. A place for exercise should be selected where there is a form of exercise congenial to the individual, be it golf or cricket, hunting or fishing, swimming or cycling. Walking in a hilly country, especially amid beautiful natural conditions, is to be especially recommended. Change of air is not without danger in many physical disorders. It should, therefore, be recommended only after thorough consideration of all the factors in a given case.

8. Climate and the Nose.—Macdonald says the influence of atmospheric and other environmental states upon the function of the nose are very interesting, also that their influence as part factors in the induction of pathological conditions is highly important. The mechanism for regulating the supply of heat and water is found in the erectile tissue. In dry, cold, mountain air the nose passages become exceptionally free, the moisture secreted exceeding the requirements for saturation. In a low state of the barometer the nose becomes "stuffy," and in damp weather the turbinals are erect when they should be partially empty. Anything which favors engorgement of the veins, such as feeble heart action, chronic bronchitis, kidney disease, etc., will cause corresponding turgidity of the nasal erectile tissue. Light produces collapse of the erectile tissue. Smoke and fear have the same effect. Irritants of any kind act similarly unless their use is prolonged. Obstructive conditions of the nose are benefited by a dry atmosphere. Irritability of the nasal mucous membrane is usually more troublesome by the sea and in windy places, while the atrophic conditions are better in moist localities. The sense of smell is very susceptible to changes of climate, but it varies greatly with the general health, the digestion, and the mental equilibrium.

Proceedings of Societies.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK:

Meeting of March 16, 1908.

The President, Dr. Robert T. Morris, in the Chair.

The Death of Dr. Farquhar Ferguson.—The following report was presented and adopted:—

Dr. Farquhar Ferguson, known to most of us as Dr. Frank Ferguson, one of the incorporators and charter members of this association, died, after a protracted and painful illness, on December 14, 1907, at Atlantic City, N. J., where he had spent the

greater part of several preceding years.

Dr. Ferguson was of Scotch descent, and was born in 1852 in Sidney, Cape Breton Island, Canada. He received his preliminary education at Sidney Academy. At an age when many of us are well along in our medical studies Dr. Ferguson could speak only his mother tongue, Gaelic. He acquired by laborious effort an extraordinary command of the English language. How successful he was in this direction, we leave to those who have heard him in conversation, in the lecture hall, and at professional meetings. He had the unusual faculty of expressing his thoughts in the simplest phraseology and with the most complete lucidity, and his sentences were delivered with a most fascinating burr. Coming to New York shortly after his majority, his first medical training was in the New York Hospital, in the capacity of an orderly. Later, under rather adverse conditions, he matriculated at the Long Island College Hospital, whence he was graduated in 1880. In that institution, from 1883 to 1887, he occupied with distinguished honor the chair of histology and pathological anatomy. From 1883 to 1888 he was pathologist to the New York Hospital, where a few years before he was an orderly. He was also professor of pathology and clinical medicine at the New York Postgraduate Medical School, pathologist to St. Luke's Hospital, the House of Relief (Chambers Street Hospital), and Bloomingdale Asylum, consulting pathologist to the New York Board of Health, and attending physician to the Columbus Hospital. His society affiliations were numerous. He was a member of the Academy of Medicine, the Pathological Society, the Society of Medical Jurisprudence, the German Medical Society, the Physicians' Mutual Aid Association, the New York County Medical Association, and others. He married in 1890 Miss Juliana Armour, of New York, who, with seven children, survives him.

Dr. Ferguson was an indefatigable worker. He was a macroscopical pathologist and a microscopist of great ability, and at the same time a clinician of extraordinary acumen. It has always seemed to the writers, however, that his chief claim for lasting distinction was in his unusual talent for teaching. He was one of the chosen few who have the capability to clearly and convincingly transfer the results of personal knowledge, observation, and experience to the student mind, and it is one of the happiest memories of one of the undersigned that he was privi-

leged to enjoy close intimacy with and instruc-tion from this master intellect. As a man, Dr. Ferguson was clean, straightforward, honest, and upright; as a friend, he was genial, sincere, and charming; as a teacher, he won the respect, esteem, and affection of his students; as a practitioner, he was conscientious, painstaking, and discriminating. As an example of unwearying diligence and indomitable perseverance, in the face of what to many of us would seem insuperable obstacles, his life was surely an object lesson of no small import.

Here's rosemary-that's for remembrance; Here's pansies-that's for thoughts. (Signed) HUBERT ARROWSMITH, WILLIAM H. PORTER, - Committee. FREDERIC E. SONDERN,

Fracture of the Pelvis .- Dr. Archer W. Jag-GER reported a very rare case, one of fracture of the ischium from indirect violence. The patient, a man fifty years of age, with no history of any disease, in the summer of 1907 had a fall which occasioned a considerable amount of pain in the gluteal region and which incapacitated him for work for three days. After that he was apparently as well as ever. In January, 1908, while walking on the street one day, he stumbled, and, despite all efforts to regain his balance, fell prone, at full length. Upon rising he experienced a sharp pain in the upper and inner aspect of the left thigh and gluteal region, but was able to walk to his destination. There he had to sit down, and was obliged to sit on the edge of the chair. On the following morning, when Dr. Jagger first saw him, the thigh was found to be partially flexed on the leg and very painful. Upon grasping the muscles on the inner aspect of the upper part of the thigh and making pressure over the insertion of the adductor magnus, distinct crepitus was obtained. The diagnosis made was fracture of the ischium, and this was confirmed by an x ray examination. The patient was kept in bed for two weeks, and made a good recovery without further treatment. In connection with the case Dr. Jagger presented a number of x ray pictures.

The President remarked that the case, so far as

he knew, was a unique one.

Dr. Ransford E. Van Giesen said that seventeen or eighteen years ago he had had a case which resembled this in the fact that after meeting with the accident the patient was able to walk a considerable distance, when suddenly he became completely incapacitated. In his case, however, the fracture was not one of the pelvis, but a fracture of the neck of the femur within the capsule.

Progressive Locomotor Ataxia.

The Relations of Tabes and Paresis.-This topic was treated by Dr. J. RAMSAY HUNT. The importance of the relation between the two diseases, he said, was not merely clinical, but had a much deeper significance, as touching upon the underlying nature and ætiology of both. The question to be considered when the two occurred together was, Is this to be regarded as a mere coincidence, or are the two affections essentially the same in nature, differing only in their localization? The essential factor in the production of the degeneration of nerve structures (the posterior roots and posterior salis was antecedent syphilis—variously estimated at from sixty to ninety per cent. of the cases. This was not syphilis in the ordinary acceptance of the term, but, presumably, a toxic state resulting, the so called parasyphilis or metasyphilis. In paresis also, in which the degeneration occurred in the association and projection neurones of the cerebral cortex, there was the same antecedent history of syphilis—this occurring, according to Mendel, in seventy-five per cent. of the cases. This relation to syphilis constituted an important bond of union between these two affections, so frequently found associated. In cases where they were thus associated, sometimes one, and sometimes the other appeared first, and in still other instances the two occurred simultaneously. Taboparesis, as it was called clinically, was so frequently met with that the combina-The number tion could not be merely accidental. of cases of tabes resulting in paresis, however, was much smaller than of those of paresis developing into tabes. Among 164 cases of locomotor ataxia treated in the nervous clinic at Cornell University Medical College during the past six years, only sixteen presented the mental or somatic symptoms of general paresis.

As to the pathology of taboparesis, while opin-

ions had differed considerably heretofore, at the present time the weight of pathological evidence tended to regard the lesions as similar in nature to those occurring in simple tabes or uncomplicated paresis. It was interesting to note that in certain cases of tabes, which had presented no demonstrable mental symptoms during life, pathological changes were found in the cerebral cortex which were histologically similar to those found in paresis, only much less marked in degree. The existence of such alterations in the cortex of tabetics was a further evidence of the intimate kinship existing between the two affections. Such findings might also be regarded as furnishing the anatomical basis for a group of tabetic cases which presented very mild symptoms of mental change and deterioration. In these, paresis might be said to be present, but in a slumbering state. In comparatively rare instances other forms of mental alienation, such as paranoia, manic, depressive insanity, dementia præcox, and mental states following drug addiction, were found associated with tabes. The fact was also to be emphasized that in the course of tabes mild mental aberrations might develop upon a neurasthenic basis which were entirely curable by appropriate therapeutic measures; and such conditions were likely to be the cause of great anxiety on account of their resemblance to the clinical picture observed in the earlier stage of paresis-the so called præparesis. This resemblance might be so close that the subsequent course of the case would alone furnish a satisfactory solution of the question. Having mentioned the various groups of cases as given by Nageotte, which presented nearly every possible transition and combination, from simple tabes to paresis, Dr. Hunt

ble transitions and combinations of the spinal cord and cortical localization were found clinically. The Bladder in Tabes was the title of a paper by Dr. J. BEXILLY SOUTH (to be published).

stated, in conclusion, that it might be said that tabes,

paresis, and taboparesis did not differ essentially in

ætiology, nature, or pathology, and that all possi-

Laryngeal Involvement in Tabes.—This paper was read by Dr. W. FREUDENTHAL, who said that for the past three years he had been examining the larynx in all the cases of locomotor ataxia coming under his observation at the Montefiore Home and elsewhere, a very large number in all. He described the various abnormal conditions met with and stated that his investigations justified the conclusion that laryngeal involvement was much more frequent

than had heretofore been supposed. Present Methods of Treatment.-This paper was read by Dr. S. WACHSMANN. In the management of any affection, he said, it was always well to bear in mind that it was not the disease which was to be treated, but the patient, and, as regarded locomotor ataxia, he had become more and more convinced that our efforts ought to be directed more toward aiding the patient in his battle against the malady than to exhausting our skill in trying to stop a pathological process which, while slow, was apparently irresistible. Although the majority of authors seemed to agree upon the assumption that all true cases of tabes were due to syphilis, occasionally there were still heard dissenting opinions, based upon theoretical considerations and absence of corresponding findings in the history or autopsies. On account of the overwhelming frequency of clearly syphilitic cases, it had been the practice, at the Montefiore Home, to give a course of antisyphilitic treatment at the outset in all instances; but he was not prepared to state with any degree of accuracy that this treatment had ever staved the pathological process, or produced an appreciable improvement in the patient's condition. Besides antisyphilitic treatment, there were very few means of attacking the process, these being mostly of a nature tending to tone up the constitution and thus enable the system to resist the progress of the dis-Among them were hydriatic and electric treatment, and there seemed to him to be little doubt that both these agencies had repeatedly produced at least temporary relief, so that the process became stationary for a considerable number of years. This opinion, however, could not claim the indisputable correctness of statistic evidence, since it was well known that cases sometimes became stationary without any treatment. Of all electrical applications, sparks from the static machine had seemed to be followed by the best results. Massage was contraindicated in all cases of tabes, as the muscular tone was apt to be so greatly diminished that it could not respond to the manipulations, and vigorous massages had been known to produce tears in the muscles, and other accidents. The exceptions to the rule against massage were malformations, such as contractures of the toes from lack of exercise, and static œdema. Here, careful manipulations might be of service, but the massage should be applied only to the joints and distal circulation-

As it was an unsatisfactory task to attack the pathological process, we had to do the next best thing, namely, combat the symptoms, just as we sometimes treated hyperpyrexia if we could not eliminate the cause of the pus. The most distressing features of the disease which required treatment might be grouped as follows: The sensory

symptoms, the paralytic, the spasmodic, and the ataxic. In addition, we had to consider the genitourinary symptoms. As to the sensory symptoms, it was not so much the anæsthesias which needed attention as the paræsthesias and hyperæsthesia. The trophic lesions were either ulcers or changes in the joints or bones (including spontaneous fractures), and these required surgical or orthopædic treatment. The Hessing corset and all apparatus of similar intent were to be condemned because they destroyed whatever was left of muscular energy by reducing the muscles of the trunk to inactivity; but the hypotonic conditions of recurvation of the knee and drop foot were benefited by suitable orthopædic appliances, which prevented stretching of the weakened muscles without immobilizing them. The pain especially needed alleviation, and among the innumerable drugs which had been employed only a few had stood the test. For the lancinating pains the following combination had proved invaluable at the Montefiore Home: Antipyrine, 10 grains; acetanilide, 5 grains; caffeine citrate, 2 grains. It was most agreeably administered with an effervescing powder. The girdle pains and the various neuralgias, as well as intercostal pains, as a rule, yielded most readily to the salicylates, especially aspirin in repeated doses of 10 grains. Heat and cold (sometimes one, sometimes the other) had the best effect when used in the form of hydriatic applications. Gastric crises were best treated by means of repeated doses of cerium oxalate (2 to 3 grains), the external application of heat, and, if possible, lavage; while the intestinal crises, usually occurring in the shape of explosive diarrhoea following prolonged constipation, mostly required opium in the form of suppositories. The very troublesome urinary incontinence the speaker had seen improved in one or two instances by lumbar puncture. The eye symptoms (muscular palsies and optic atrophy) were usually treated by strychnine and large doses of iodides.

The ataxia, or incoordination, could not be treated by drugs, but was favorally influenced by total abstinence from tobacco and alcohol. The actual treatment of this symptom was a systematic development of the deep muscular and articular senibility. Efforts in that direction had long been made by various authorities, but the best results had now been obtained by the elaborate and very ingenious system of reeducation devised by Frenkel. This method depended to a great extent on the intelligence and will power of the patient, for without his cooperation the physician would fail in his efforts to teach the tabetic again to use his muscles properly. The attempts of the patient to gain and retain his equilibrium required in the beginning great effort on his part, as indicated by a rapid increase in the number of heart beats and respirations-apparently a purely psychic phenomenon. Great care therefore had to be taken not to overtax the heart. After patients had learned how to stand, they learned to raise the feet successively, and then how to walk and how to turn. Later on, they learned to stand and walk without the aid of sight. When the ataxia had affected the upper extremities a similar method was applicable, cleverly designed apparatus and tools being employed. While Dr. Wachsmann

did not hesitate to recognize the great value of the Frenkel method, he said he would like to add that its only merit consisted in the well systematized course of lessons which made it more interesting and attractive both for the physician and for the patient. In reality we did not need strips of linoleum with mysterious lines, footprints, and geometrical figures, or, again, apparatus or tools, as patients could be instructed without these. In closing, he invited any who might be interested in getting an idea of the practical application of Frenkel's method to visit the Montefiore Home and see the exercises.

At Dr. Wachsmann's request Dr. E. A. FRUCHT-HANDLER then gave a demonstration of two female tabetic patients who had been taught by the Frenkel method. They walked and turned readily, even with the eyes closed, and it was stated that one of them, a young woman of twenty-three, who had had the locomotor ataxia for four years, was able to

walk three miles alone.

Dr. A. D. ROCKWELL said that undoubtedly the chief cause was syphilis, and that if all cases of syphilis could be properly treated, we should see much less of tabes than now. He did not think much could be done to affect the diseased process, but agreed with Dr. Wachsmann that a great deal could be done to relieve the symptoms. The static spark he had found useless for treating pain, and for this purpose he was accustomed to rely upon two agencies, the galvanic current in great strength and heat and light in the form of the arc light. The ultra violet ray, which he had experimented with by request, he had found of no benefit whatever.

Dr. W. B. PRITCHARD said that at the present day the consensus, both among alienists and among neurologists, was in agreement with the views expressed by Dr. Hunt. Paresis was the superior equivalent of tabes, as tabes was the inferior equivalent of paresis. Paresis of late seemed to be somewhat different from what it was formerly, and more and more frequently we saw in the medical journals the question, Is paresis curable? The duration of the disease used to be set down as three years, but now we met with cases which lasted ten or twelve years. Also, the grandiose conceptions which were once regarded as such a constant and prominent characteristic of the affection were often found to be entirely lacking. As to tabes, there did not appear to be much change, but, at the same time, within the last few years it had seemed to him that more anomalous cases were met with. He could not assent to the view that syphilis was the universal cause of the disease, as he had seen a number of cases in which he was as sure as of anything in medicine that syphilis was not a factor. Larvngeal crises (to which he would confine stridulous coughing and voice changes) were rare in his experience, and he could recall but three instances. In the treatment the personal equation, as Dr. Wachsmann had said, was all important, dominating the whole situation. The Frenkel method he considered a marvel of conscientious study and patient labor, to which he had never seen anything else approach, but the trouble with it was that it was too perfect, too scientific. It was impossible to carry out all the elaborate details set down. Before Frenkel had devised

his system there had been courses of exercises for tabetics, and there was a great deal of value in the principle.

Dr. H. G. PIFFARD said that, while the static spark sometimes relieved pain, it also gave pain. As to the ultra violet ray, nothing could be expected of it as it could not even penetrate the skin. In two cases of tabes he had employed with very gratifying results a method which was wholly new, namely, the use of the d'Arsonval high frequency currents. The first patient was a man, fifty-three years old, who had been obliged to give up business, both on account of ataxia and on account of mental failure. At the end of two months his pains were decidedly improved, and instead of coming in a cab he walked from and to his house with one cane. He was then able to close up his affairs and go to Europe, and he was advised to consult Frenkel in Switzerland. The second case was in a man, about forty years of age, who had hypotonia of the muscles of the lower limbs and occasional pains, though these were not very severe. He came about three times a week for two months, at the end of which time the ataxic gait had greatly improved and the pains had for some time been absent. His general health was also much improved, and he was able to give better attention to his business. The treatment was by autocondensation.

Dr. W. M. Leszynsky said that, while the diagnosis of tabes was usually a very simple matter, in exceptional instances it was attended with difficulty. In any alleged case of cure, therefore, the question would arise, Was the diagnosis correct? As most of the cases received at the Montefiore Home had been previously treated outside, and given an antisyphilitic course, it seemed hardly necessary to repeat this in the institution. The opinion was now held that the disease was due to antibodies resulting from syphilis, and not to syphilis itself, and mercury seemed to have no effect upon the existing degeneration. The Frenkel method was very difficult to carry out except in an institution.

Dr. FRUCHTHANDLER said that many of the described by Frankel were really unnecessary, so that the method could be successfully carried out in private practice. All that was required was a large room and a working knowledge on the part of the physician of the principles involved in the system.

Wetters to the Editors.

CONCERNING THE INTERNATIONAL CONGRESS ON TUBERCULOSIS.

NEW YORK, Jugust 3, 1908.

To the Editors

The International Congress on Tuberculosis will be held in Washington from September 21st to October 12th. With the exception of those of 1876 and of 1887, it will be the first great international medical congress in the United States. There seems to be no reason why it should not prove a great success, and both the Americans who planned, favored, and prepared it and the Europeans who have been taught to expect great things from America are look-

ing forward to the congress of 1908 as an event of

the first magnitude.

Its objects are the study, prevention, and eradication of tuberculosis, the most formidable enemy of mankind, sapping its vigor and endangering its That is why in all countries both medical men and laymen have combined to search in the medical and social sciences for the root of the great evil and are looking for its gradual extinction. That is also why educated and generous citizens have come forward with financial aid and mean to par-

ticipate in the labors of the congress.

But, after all, a congress of this nature and with this programme must be carried on mainly by the medical profession, and its objects cannot be realized without the cooperation of thousands. Now, these lines have no other purpose but to draw the attention of an ever ready profession, those who have forgotten or delayed, to the fact that only a few weeks more will pass before the congress will be opened. Meanwhile the State of New York, the Empire State, had, until a few weeks ago, furnished fewer than five hundred active members. Five dollars sent to the secretary general, Dr. John S. Fulton, 714 Colorado Building, Washington, D. C., will secure membership, including admission and a copy of the Transactions of the congress. It seems that a mere reminder like this will swell the list of active members, whose duty and right appear to be to prove to the world at large, and particularly to those many foreigners who will visit us on this occasion, that America takes a prominent stand among the countries which value the health and the lives of its citizens. That is why I take the liberty of requesting you to publish this appeal to my professional brethren of this and other States.

President, Fourth Section, International Congress on Tuberculosis.

SNAKES IN IRELAND AND IN ICELAND. ANN AREOR, MICH., August 3, 1908.

To the Editors:

Many besides myself must feel indebted to Dr. Jacobi for his note on the Venerable Bede and the reference to snakes in Ireland. I had a controversy with the snake editor of a medical periodical in the silly season of a few years ago, and should like to suggest now, as I did then, that the use of the phrase comes down from Samuel Johnson, rather than Bede, and should therefore read as you say. On one occasion Johnson said he could repeat the whole chapter from the Natural History of Iceland, translated from the Danish of N. Horrobow, and did so. I had curiosity enough to look up Horrobow's work, a translation of which is in the library of the University of Michigan. You might have said the chapter closed as well as opened with the celebrated phrase, for the whole chapter (lxxiii) is as follows: "Concerning Snakes. No snakes of any kind are to be met with throughout the whole island." Chapter xliii is equally laconic: "There are no owls of any kind in the whole island." I may add that both Horrobow and Boswell are excellent hot weather reading.

GEORGE DOCK.

Book Rotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Surgery. By John Allan Wyeth, M. D., LL. D. (University of Alabama), President of the New York Academy of Medicine; President of the Faculty of, and Surgeon in Chief to, the New York Polyclinic Medical School and Hospital, etc. With 864 Illustrations. New York: Marion Sims Wyeth & Co., 1908. Pp. viii-816. (Price, \$6.)

The legend of dedication of this handsome volume, to the memory of the late Dr. J. Marion Sims, is appropriately surmounted by a fine engraving of the statue of Dr. Sims which stands in Bryant Park, an artistic tribute which the city owes largely to the enthusiasm of the late Dr. George F. Shrady. Both the statue and the dedication are fitting memorials of a great surgical genius "whose achievements," says Dr. Wyeth, "carried the fame of American

surgery throughout the civilized world."

The work may be regarded as practically a new edition of the author's Textbook on Surgery, which went through three editions, the first of which was published in 1887. It is unnecessary, therefore, to attempt an analytical review of it; the book met at once with a warm welcome, and has ever since maintained its popularity. One of its salient merits has always been the accuracy and teaching efficiency of its pictorial illustrations. This feature is preserved in the volume now under consideration; fifty-seven of the illustrations are in colors, and many new pictures have been added. Another notable characteristic of the work is the amount of attention bestowed on minor surgery, a subject which, though of great importance, is apt to be slurred over in pretentious treatises. The book has been well put abreast of the present state of a constantly advancing branch; if we fail to find mention in it of such topics as the paraffin dam for urinary incontinence in women and castration for prostatic hypertrophy, we must say that we think their consideration has been wisely omitted. Bier's artificial hyperæmia and the treatment of tetanus by means of spinal injections of magnesium sulphate are mentioned in a properly conservative spirit.

It is to be noted that the imprint is that of a new publishing house. We wish the firm all possible success. They have done their work well in this instance, and we particularly commend them for having withstood the present rage for desecrating Latin words by the suppression of diphthongs.

Borderland Studies. Miscellaneous Addresses and Essays Pertaining to Medicine and the Medical Profession, and Their Relations to General Science and Thought. Volume II. By George M. Gould, M. D., Formerly Editor of the Medical News, etc. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 311.

It is eight years since the first volume of this series appeared, but the various addresses and essays have so little connection among themselves that this volume is quite as readable without its predecessor as it would be with it. Most of the subjects treated of have very little to do with medicine or the medical profession. The first essay, which is the best of the lot, entitled The History of the House; the Struggle for Fresh Air and Light, is, indeed, but very remotely relevant to the second

term of its title.

Dr. Gould is nothing if not earnest, but his earnestness often leads him into intolerance of those who do not agree with him, and this is apt to be manifested by vituperation, the author appearing to take every man for an ass who ventures to dissent from his dicta and to forget the homely old saying that more flies are caught with honey than with vinegar. If the reader will make allowance for this idiosyncrasy, he will take pleasure in reading the

Die Hautkrankheiten. Von Prof. Dr. Jarisch. Zweite, vermehrte und neubearbeite Auflage. Bearbeitet von Prof. Dr. Rudolf Matzenauer. Wien und Leipzig: Alfred Hölder, 1908. Pp. 1110.

The first edition of this book appeared in 1900 as volume xxiv of Nothnagel's Specielle Pathologie und Therapie, and received a warm welcome by the medical profession and the reviewers. Since then its distinguished author has died. In the present edition Professor Matzenauer has preserved the original clinical descriptions and as much of the text as possible. He has carefully and critically revised the sections on pathological anatomy and on treatment. The articles on tuberculides, Röntgen ray dermatitis, pityriasis lichenoides chronica, lichen simplex, and blastomycosis are either entirely 'rewritten or new. On account of careful pruning and the liberal use of closely set type, there are but sixty more page in this than in the previous edition. Part of the economy of space has been dearly bought by omitting fifty-three illustrations, the present edition having but seven.

To produce so thorough a treatise meant the expenditure of a vast amount of time and labor by the author. The result was well worth the work. Unlike many German authors, Jarisch appreciated the fact that there were other observers than his countrymen, and referred to many French, English, and American writers. After each article is placed the literature, arranged alphabetically according to the

names of the authors.

After sixty-three pages on the anatomy of the skin, symptomatology, and general diagnosis, the skin diseases are presented in groups, sometimes on the basis of ætiology, sometimes on that of their pathology, and again simply according to the structure affected, like the hair or the nails. It is well recognized that all attempts at classification of skin diseases are more or less failures. The grouping here adopted leads to some strange combinations. For instance, under folliculides we find acne, acne keloid, and furuncle, while under impetigo are placed farcy, actinomycosis, blastomycosis, and

Many pages are devoted to the discussion of debatable questions. These are interesting and instructive reading, but unusual in a textbook. subject of pathology is presented at length, and the sections on the treatment of the various diseases are for the most part full of helpful advice. While the uses of x rays are indicated, we fail to find mention of radium or the high frequency currents. The subject of the tuberculides is well presented and at length. The use of x rays in the treatment of hipus

vulgaris is advised against, and the warning is given that they not infrequently seem to cause the development of epithelioma on the lupus patches. On the other hand, the Finsen light method is endorsed, and to it is credited a proportion of eighty-five per cent. of cures against one of six and a half per cent. by other methods. Lupus erythematosus is placed among the tuberculides on account of some possible connection between it and lupus vulgaris, though the author, or the editor, admits that such a connection has not been established. The subject of blastomycosis is dismissed with scarcely two pages, and the writings of Dr. J. N. Hyde seem to have been overlooked. It is satisfactory to note that acute pemphigus in infants is regarded as really either the bullous form of impetigo or as due to septic infection. It would be better, it seems to us, if dermatologists would agree to drop the term pemphigus entirely in connection with these cases. It is also interesting to note that our author accepts the prevailing opinion that the lichen ruber acuminatus of Hebra is identical with the pityriasis rubra pilaris of the French.

We take pleasure in commending once more this excellent textbook. It is one of the best and most exhaustive treatises written by a single author, one who was both sane and sound. It is a cause of regret that Professor Jarisch did not live to revise it himself, and enjoy the words of commendation by his fellow workers; but the delicate task of editing another man's book has been well performed by

Professor Matzenauer.

Miscellany.

Pancreatitis Resulting from Gallstone Disease.-William J. Mayo remarks that in acute pancreatitis there is a sudden onset and the pancreatitis is ushered in by agonizing pain in the upper abdomen, with collapse, followed by extreme pros-tration. The pulse becomes quick, there is some elevation of temperature, with nausea, vomiting, and rapid abdominal distension. The acuteness of the symptoms suggest obstruction, which is belied by the ability to secure the passage of flatus. patients are usually elderly, obese, and often have alcoholic histories. On opening the abdomen, the pancreas is found greatly enlarged, softened, and indefinite in outline, with more or less free peritoneal fluid and pea like areas of fat necrosis. If gallstones exist they should be removed quickly and the gallbladder drained. In all cases where free fluid is found in the peritoneal cavity temporary abdominal drainage should be established. Of three acute cases of pancreatitis, two patients recovered, one patient died. Nine patients with subacute cases recovered. Chronic interstitial pancreatitis may extend over years of time without producing such symptoms as readily to distinguish the complication from the original disease, but if its possibility is borne in mind and careful search made, evidence can be elicited to show the nature of the disease, and if pancreatic changes are present it indicates an early resort to surgical interference. Jaundice is one of the most marked symptoms and may last for months or years. The emaciation is more extreme and the

pigmentation of the skin is more marked than in simple, uncomplicated common duct stones. As the antecedent disease is most often gallstones, an early history of this condition can usually be obtained. A distended gallbladder may occur if the biliary passages are normal, but such distension, with jaundice, usually indicates cancer rather than chronic pancreatitis. In a thin patient the enlarged pancreas can sometimes be felt as a hard mass lying transversely across the upper abdomen. Careful examination of the stools gives much important evidence. They are pasty, very large on account of undigested food, and contain quantities of fat. Even if there is no jaundice, the bile, which without pancreatic juice gives only a light yellow color to the stool, is not sufficient to stain the great quantities of fat which are passed off, so that frequent large, light colored, greasy motions, without jaundice, are indicative of pancreatitis. Estimation as to the quantity of stercobilin should be made. Undigested muscle fibre can often be detected in the stool. The presence of chronic interstitial pancreatitis does not greatly influence the prognosis after gallstone operations, although there is undoubtedly a much greater tendency to hæmorrhage than without the pancreatic complications. For this reason the author and his brother have used either the chlorid or lactate of calcium to assist coagulation of the blood before and after operation. They are, however, in doubt as to its actual value. The necessity of clearing out all of the calculi, especially from the common duct, cannot be emphasized too strongly. Stones are especially liable to be lodged under the overhanging head of the enlarged pancreas, so that they may easily be overlooked, as the Mayo brothers have found by experience. As a matter of fact, neither probe nor scoop can be depended on to "feel" a gallstone in this situation, and they have never rested satisfied until they have freely opened the common duct and, if possible, inserted a finger into its lumen, making sure that no gallstone has escaped detection. In the same way, in the majority of cases, the hepatic duct and the entrance to its right and left primary divisions can be searched for calculi having their origin in the gallgladder, but which have been crowded back into the hepatic ducts. After clearing the ducts of stones, a large, malleable probe should be passed through the common duct into the duodenum, so as to secure good, thorough dilatation to permit the escape of any hepatic duct stones which may come down later. Hepatic duct stones, as a rule, are not large, and if free drainage into the duodenum exists, even for a few days, they may find their way out; otherwise they might be retained in the common duct, necessitating a secondary operation. Cholecystostomy or cholecystenterostomy are the indicated procedures. The latter operation has the advantage of equally free drainage and at the same time maintaining the influence of the bile in intestinal digestion. In the Mayos' experience, when the common duct contained stones, the removal of them with temporary external drainage has resulted in the symptomatic cure of the pancreatitis. If there are no stones in the common duct or gallbladder, other things being equal, they have preferred cholecystduodenostomy, and out of twenty-four cholecystenterostomies nine were performed for this cause.-The Journal of the American Medical Association.

Official list of changes of stations and duties of com-missioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending July 30, 1508:

BAILLY, C. WILLIAMS, Acting Assistant Surgeon. Granted leave of absence for seven days, from July 28, 1008

BAIRD, W. A., Acting Assistant Surgeon. Granted leave of

absence for sixteen days, from July 10, 1008 Banks, C. E., Surgeon. Granted leave of absence for

twenty days, from August 23, 1908.
Blue, Rupert, Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board.

San Francisco, Cal., August 3, 1908.
Brincherhoff, W. R., Director Leprosy Investigation Station. Granted leave of absence for thirty days, from August 3, 1908

BRYAN, WILLIAM M., Assistant Surgeon. Granted leave of absence for one day, July 21, 1908, under paragraph 191 Service Regulations

CARRINGTON, P. M., Surgeon. Granted leave of absence for sixteen days, on account of sickness.

Cobb, J. O., Surgeon. Granted leave of absence for seven

days, from July 29, 1908. Gibson, F. L., Pharmacist. Granted leave of absence for

thirty days, from September 8, 1908, and excused without pay for one month and ten days, from October 8,

GLEASON, C. M., Acting Assistant Surgeon. Granted leave of absence for twenty days, from August 1, 1908.

KENNEDY, S. R., Acting Assistant Surgeon. Granted leave of absence for thirty days, from July 23, 1908.

KING, W. W., Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board,

San Francisco, Cal., August 3, 1908. McIntosh, W. P., Surgeon. Granted leave of absence for

one month, from August 14, 1908. Miskimon, Robert, Pharmacist. Gran

Granted an extension of leave of absence for seven days, from July 27, 1908.

SMALL, E. M., Acting Assistant Surgeon. Granted leave of absence for four days, from June 20, 1908. STEARNS, H. H., Acting Assistant Surgeon. Granted leave of absence for one day, on account of sickness, July 13, 1908.

STIMSON, A. M., Passed Assistant Surgeon. Granted leave of absence for one month and fifteen days, from

August 17, 1908. Stoner, J. B., Surgeon. Granted leave of absence for one

day, July 26, 1908. VILLOLDO, P., Acting Assistant Surgeon. Directed to proceed to Cienfuegos, Cuba, for temporary duty, upon completion of which to rejoin his station at Havana.

WATKINS, MCD., Acting Assistant Surgeon. Granted leave of absence for one day, July 29, 1908.

Wertenbaker, C. P., Surgeon. Directed to proceed to Wachapreague and Cape Charles City, Virginia, for the purpose of examining keepers and surfmen of the Life Saving Service

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the Unifed States Army for the week ending July 18, 1908:

GIRARD, J. B., Colonel. Detailed to represent the Medical Department of the Army at the Fifth Pan-American

Medical Congress at Guatemala, August 5th to 10th.

KENDALL, W. P., Major. Ordered from Fort Ethan Allen,
Vermont, to Fort Ontario, N. Y., for temporary duty.

KIKEPATRICK, T. J., Major. Granted leave of absence for
one month, about August 15th.

Moncrief, W. H., Captain. Granted leave of absence for

two months, when services can be spared, with permission to ask extension of one month.

The following named first lieutenants of the Medical Reserve Corps, recently appointed from contract surgeons, with rank from July 7, 1908, were ordered to active duty in the service of the United States, July 28, 1908: E. A. Anderson, J. K. Ashburn, H. C. Bierbower, I. C. Brown, P. D. Brown, W. E. Brown, G. F. Campbell, G. R. Clayton, G. W. Cook, C. W. Cullen, W. O. Cutliffe, O. F. Davis, S. C. De Krafft, A. C. Delacroix, W. F. de Niedmann, C. T. Dulin, H. W. Eliot, J. A. Escobar, E. J. Farrow, Frederick Iladra, W. E. Hall, C. H. Halliday, J. R. Hereford, T. G. Holmes, M. E. Hughes, T. W. Jackson, F. E. Jenkins, E. K. Johnstone, E. C. Jones, G. B. Jones, P. S. Kellogg, J. F. Leeper, J. C. Le Hardy, Robert Lemmon, D. P. McCord, H. C. McLeod, S. B. McPheeters, J. N. Merrick, F. H. Mills, J. R. Monnt, W. H. Myers, J. B. Pascoe, E. W. Patterson, Howard Priest, C. H. Richardson, W. E. Sabin, J. M. Shepherd, R. E. Sievers, J. T. H. Slayter, R. D. LOCAL AND SURGICAL TREATMENT OF CHRONIC DIARRHŒA.

With Description of a New Operation for Irrigating Both the Large and Small Intestines.*

By Samuel G. Gant, M. D., LL. D., New York,

Ex-President, American Proctelogical Society: Professor of Diseas of the Rectum and Anus, New York Postgraduate Medical School and Hospital.

Chronic diarrhœa is of common occurrence, its progress is insidious, and its results far reaching. This class of patients not only suffer from exhaustion and loss of weight brought about as a result of frequent evacuations, but also from nervous phenomena, anæmia, skin eruptions, headache, and other manifestations of intestinal autointoxication and underfeeding.

In recent years I have had unusual opportunities for studying this complaint, and my observations have led me to believe that the primary cause of chronic diarrhea is situated in the colon, and more especially the sigmoid flexure and rectum, very much more frequently than is generally supposed. In some instances disease in the lower bowel is secondary to and induced by pathological lesions of the stomach or small intestine, which excite an irritating discharge that is constantly poured into the colon. It sometimes happens, however, that disease thus produced in the colon and rectum remains to continue the diarrhea after the original cause has been removed.

Usually a proctoscopical or sigmoidoscopical examination will reveal the location and nature of the irritation which excites the frequent stools, but when it does not, if a local or irrigating treatment is substituted for internal medication, and the frequency of the evacuations is diminished, it demonstrates that the cause of the diarrhoa is located in the lower bowel. While endeavoring to make a diagnosis it is well to bear in mind that a chronic diarrheea may be induced by colitis, stricture, benign or malignant tumors which encroach upon the lumen of the gut, foreign bodies, a deviated coccyx, fæcal impactions and adhesions, angulations, or other mechanical obstruction which occludes or keeps the intestine in a state of constant irritation. Of these ætiological factors in chronic diarrhœa, we are at present interested only in colitis.

Colitis is by far the most common cause of this 'Read before the Medical Association of Greater New York, Nov.

 complaint, and it may be catarrhal, tuberculous, dysenteric, syphilitic, or gonorrhœal in character.

Chronic inflammation of the mucosa may excite frequent discharges of mucus, but does not greatly increase the number of daily evacuations; but when the membrane becomes ulcerated the frequency of the stools is immediately increased. When the ulcers are small and far apart, the daily movements will be few; on the other hand, when they are multiple and of large size, the patient will be compelled to spend most of the time in the toilet.

As a general rule, when ulceration is extensive it most frequently involves the sigmoid or the rectum.

If chronic diarrhea, as I believe in the vast majority of cases, is induced by ulcerative lesions situated in the colon, then it appears to me that the usual method of treating this complaint with drugs internally administered is wrong and should be discontinued.

Medicines judiciously used will lessen the number of evacuations and sometimes arrest a violent attack of acute diarrhea by drying up the secretions or preventing peristalsis, but in the chronic form I have rarely known them to effect a permanent cure, but have on many occasions witnessed the return of the diarrhea as soon as the immediate effects of the drugs had worn off.

Chemicals like bismuth and chalk, opiates, intestinal antiseptics, mild astringents, and other remedies so frequently prescribed for the relief of this condition, are harmful to the system in many ways, and patients frequently become addicted to them. For these reasons and because of their ineffectiveness in healing lesions responsible for the frequent stools, they should be discarded in the treatment of chronic diarrhea except in cases where, for any reason, direct treatment of the bowel is refused or found impracticable.

The local treatment of colitis may be nonoperative or surgical. Nonoperative measures, such as controlling the diet, having the patient remain quiet, and colonic irrigation, should be given a fair trial before operative procedures are resorted to. The success of the nonoperative treatment depends mainly upon the thoroughness with which the bowelts cleansed. The frequency of the evacuations diminish as soon as the irrigating fluids hereafter to be named are correctly used. Many physicians and nurses believe it an easy matter to insert a colon tube to administer a high enema or irrigate the intestine. Owing to the obstruction to the passage of the tube offered by the sphincter muscle the rectal valves, O'Beirne's sphincter, the flexures of

the bowel, and the straining of the patient, it is most difficult in many instances to introduce a soft rubber pipe well up in the colon. It does not follow by any means that the tube has reached its destination simply because it disappears within the bowel, for the reason that it not infrequently doubles upon itself within the rectum or sigmoid flexure. When there is difficulty in inserting the pipe it can be done quickly by introducing the proctoscope, locat-

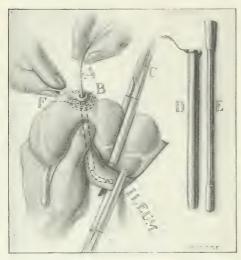

Fig. 1.—Showing method of introducing the catheter into the ileum in the author's colostomy, with an arrangement for irrigating the small intestines.

ing the entrance to the sigmoid, and then pushing it through the instrument and into the colon.

Usually after the bowel has been irrigated for a week, the frequency of evacuations (sometimes ten to thirty) are reduced to one or two daily. In those cases where improvement is less marked, it indicates that there is an enterocolitis, or that the solution is not reaching ulcers situated in the upper part of the large bowel.

The irrigating treatment is usually effective in all varieties of colitis, but naturally takes a longer time to overcome a tuberculous than it does other types

of ulcerative colitis.

Following the treatment of diarrhoea by enteroclysis, there is always a marked improvement in the local and general condition of the patient, irrespective of the nature of the solution employed; apparently much of the benefit derived from this procedure is due to the mechanical effect of the fluid in cleansing the ulcers and freeing the mucosa of toxincs, irritating discharges, and débris. In the beginning the colon should be irrigated twice daily, but later on in proportion as the ulcers heal the treatment should be diminished to one daily or two or three times weekly, according to indications. I have obtained good results following daily irrigation of the bowel with hot and ice water, and solutions containing boric acid, common salt, quinine, ichtigal, form of blued, colonless hadrasts, Lamerra

and soda, silver nitrate, and other remedies too numerous to mention.

When ulceration is slight or moderate in degree, the solutions do well when used very weak, but when it is extensive, as indicated by very frequent evacuations containing pus and blood, they should be used stronger until there is evidence of improvement. When there is considerable bleeding I begin the irrigation with a solution of silver nitrate I to 500, and gradually decrease the amount of silver each day as healing takes place.

The stools of some persons suffering from chronic diarrhea are exceedingly offensive; in such cases, an occasional irrigation with a one or two per cent. solution of ichthyol will serve both to deodorize the movements and to cure the ulcers.

Some patients complain of colic, enterospasm, or general soreness of the bowel at times; under such circumstances much can be done to render them more comfortable and to lessen intestinal irritation by hot abdominal fomentations and the high injection into the colon of 4 oz. (120 c.c.) of warm liquid paraffin or oil containing 20 grains (1.2 grammes) of bismuth, which is allowed to remain in the bowel over night.

When nonoperative measures fail to cure diarrhea after a few weeks' or months' trial, one of the surgical operations devised for the relief and cure of ulcerative lesions of the colon should be performed. Fortunately for this class of sufferers, the surgical procedures commonly resorted to for this purpose are usually effective and involve but little danger. The following operations have been used with more or less success in the treatment of simple and ulcerative colitis inducing chronic diarrhea?

1, Resection of the colon; 2, colostomy; 3, appendicostomy; 4, cæcostomy with irrigation of the small intestine (Gant's operation); and 5, intestinal exclusion.

Resection of all or a part of the colon is occasionally justifiable in the treatment of colitis, and is indicated when the functionating power of the gut is irretrievably lost as the result of exhaustion, extensive ulceration, cicatrices, strictures, or multiple polyps.

I have reported a case of chronic diarrhea of years' standing, caused by colitis and multiple strictures, which was cured by excising the rectum, sigmoid flexure, and the descending and right half of the transverse colons.

From my experience with this and other cases I would not hesitate to remove the entire colon down to the rectum under such circumstances mentioned. In such deplorable cases, colostomy and other methods of treatment do not offer to the patient any hope for permanent relief, while complete cradication of the disease does, and the operation is not nearly so difficult or dangerous as one who has not performed it would believe.

Colostomy has been successfully employed many times in the treatment of chronic diarrhea due to intestinal ulceration, but this procedure has not become popular because of the difficulty experienced masking an artificial anus which will prevent leakage of gas and faces, and further because of the

danger which accompanies the operation for restoring the continuity of the intestines after the colitis has been cured. The colostomy opening may be made at any point along the colon, but by preference the anus should be established high up, in order to insure its being above the disease, otherwise the irrigation may be incomplete and unsuccessful.

In making a colostomy in this class of cases it is not necessary to make a perfect spur, as is done when the operation is performed for the relief of cancer or other disease causing chronic obstruction, because the bowel can be made to heal by frequent flushings in spite of the fact that the fæces pass over the diseased gut. I mention this because it is very much easier to repair a small opening in the bowel made for irrigating purposes than it is to make an end to end or lateral anastomosis and close an artificial anus, where the fæcal current has been completely diverted from its normal course.

The technique of colostomy has been greatly improved (see Gant's Diagnosis and Treatment of Diseases of the Rectum, Anus, and Contiguous Textures, third edition) recently, and patients operated upon by modern methods have a much better control over the artificial anus than was formerly the case, an advantage greatly appreciated by the patient where the opening is to be permanent.

In 1892 Gibson' suggested a novel way of performing right inguinal colostomy, which has been successfully employed in the treatment of ulcerative lesions of the lower bowel. This procedure has met with favor because it permits a thorough bowel irrigation and at the same time in a measure prevents the involuntary escape of fæces.

The main point of vantage in Gibson's operation is to be found in the valvelike arrangement formed by the placing of three layers of Lambert sutures in the cæcum, above and below the opening, which serve to invert the wall of the gut at the sides of the catheter. He leaves the ends of the last tier of stitches long and anchors the cæcum with them.

On one or two occasions I have observed the fæces escape beside the tube on the sides which were not infolded. This has led me to modify this operation by forming a circular cone shaped valve, which is done by introducing three or four sero-muscular purse string sutures, which, when tied, invert the bowel layer by layer equally on all sides of the catheter (Figs. 1 and 2, F).

Appendicostomy at the present writing is the most popular of all the surgical procedures which have thus far been devised for the relief and cure of

chronic diarrhœa.

I have elsewhere (Boston Medical and Surgical Journal, September 6, 1906) reported eight cases of chronic diarrhea of different types treated by appendicostomy and through and through irrigation. Since then I have handled in the same manner twenty-seven other individuals suffering from ulcerative colitis.

One of my earlier patients died as a result of extensive sloughing of the cæcum in the neighborhood of the appendix. In the remaining thirty-four patients the number of daily stools rapidly diminished immediately following inauguration of through and through irrigation, and the general appearance of my patients improved correspond-

ingly. At the end of a week or ten days, with two exceptions, they did not have more than two or three movements daily, and had gained considerable in weight; at the end of from four to twelve weeks they had fully recovered from their diarrhoea and the manifestations arising from the consequent autointoxication. In the two patients referred to who did not do so well I could not get the evacuations below three or four in twenty-four hours, and occasionally, after experiencing discomfort in the centre of the abdomen, they would have what they called an "explosion," which would be followed by the discharge of a large number of soft or fluid movements and gas. A careful study of these subjects and their stools convinced me that they suffered both from catarrh of the small intestine and ulcerative colitis. Due attention was then paid to the treatment of the condition in the small bowel, while irrigation was kept up in the colon, and in a short time both made a satisfactory recovery.

The appendicular outlet was kept open in the different cases for a time varying from five weeks to six months, and in the entire series of cases the diarrhœa did not return after the opening was closed with two exceptions. In both the irrigation had been discontinued within two months of the time of operation. From this experience I have concluded that it is inadvisable to close the opening or remove the appendix sooner than three or six months following the operation. Patients do not insist on early closing, as a rule, because the opening is small, and they are rarely bothered with the involuntary escape of gas and fæces. In some instances the appendicular opening remained free throughout the treatment, but in others it was found necessary to insert a small catheter to keep it from

becoming occluded.

After a cure had been effected, in a few cases the appendicular opening closed spontaneously; in others the aperture was sealed by destroying the mucosa with chemicals, an electrical or a Paquelin cautery, and in the remainder, under local anæsthesia, the appendix was freed, ligated, and excised without entering the free peritoneal cavity, and the wound

closed by plain catgut.

I have called attention to the good points of appendicostomy, but now I wish to point out a few disadvantages of this procedure. When the appendix is small, short, strictured, or is firmly bound down by adhesions, it is useless for irrigating pur-The appendix occasionally has a tendency to slip into the abdomen during postoperative vomiting and early attempts at irrigation. It has been known to become necrotic, and in one case of my own death followed from sloughing of the cæcum at the appendicular attachment, presumably as the result of tension. On account of its small size, the appendicular opening requires considerable attention to prevent its closing. Occasionally considerable time is lost in searching for the appendix and freeing it from neighboring structures.

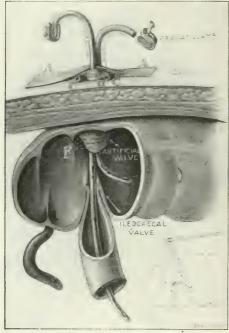

Finally, it may be stated that appendicostomy is not a suitable operation to employ when there are both an ileitis and ulcerative colitis, which play their respective parts in causing the diarrhæa, because this procedure permits of colonic irrigation

only.

Cacostomy. I have successfully employed cacos-

¹Reston Medical and Surgical Journal, exly, 1902

tomy twelve times in the cure of chronic diarrhœa. In six cases the procedure of Gibson, which has already been described, was followed, and in the other six my method was practised. According to my plan, cæcostomy may be resorted to in all cases of chronic diarrhœa which are suitable for appendicostomy and those which are not, because of the diseased or deformed condition of the appendix, and also cases where both the small and large intestines are diseased. Formerly I was greatly prejudiced in favor of appendicostomy, but a larger experience has convinced me that cæcostomy alone, and more especially when employed with small intestine irrigation, has a much wider field of usefulness than is generally believed at the present writing.

The z S every arrange of and methods of holding and closing the catheters in the author's colostomy.

Both excostomy and appendicostomy are desirable procedures because they are effective, are not dangerous, can be performed quickly, and leave few if any undesirable sequelæ.

Personally I have no more hesitancy in advising these operations for the relief of chronic diarrheea

than appendectomy for appendicitis.

I will now for the first time describe what I believe to be a new and effective way of irrigating both the small and large intestine through the same opening in the execum, which, for the want of a better name. I have designated excussions with an arrange most few translation both the large and small intestion of child constitutes.

Broth d cribed, the steps in the technique of this quarter are as follows: First step: Through a two inch intermuscular incision made directly over it the cæcum and the lowermost part of the ileum are withdrawn and the edges of the wound covered with gauze handkerchiefs.

Second step: The execum and ileum are stripped clear and clamped (Fig. 1, C) with forceps covered with rubber tubing, in order to prevent soiling of the wound when the bowel is opened.

Third step: Four seromuscular purse string sutures are inserted on the anterior surface of the excum at or outside the longitudinal band directly opposite the ileoexcal valve (Figs. 1 and 2, F). Using the knife for the outer coats and the scissors for the mucosa, the bowel is quickly opened within the suture line.

Fourth step: The bowel is grasped at the juncture of the large and small intestine and held in such a way that the ileocæcal valve rests between the thumb and fingers (Fig. 1). A Gant catheter guide (Fig. 1, B and D) is then introduced through the opening and directed across the cæcum, where it is guided through the ileocæcal valve into the small intestine by thumb and fingers of the left hand.

Fifth step: The guide is held by an assistant while the obturator (Fig. 1, A) is removed and a No. 12 catheter (Fig. 2, A) is introduced into the small bowel. The guide is then removed and the catheter anchored to the cæcum by a catgut or silk suture to prevent its slipping.

Sixth step: A short piece of rubber tubing of the same size and three inches (Fig. 2) long is introduced beside the catheter into the cæcum for an inch (Fig. 2) or more, when both are fastened together by a narrow band of adhesive plaster, placed around them on a level with the skin (Fig. 2, B).

Seventh step: The intestinal clamps are now removed and the purse string suture is tied, which inverts the edges of the wound about the catheters. Three or four more similar sutures are introduced, the one above the other, each in its turn causing a still further circular infolding of the bowel, all together forming a cone shaped valvular project (Fig. 2, F) all around the catheters, which prevents the escape of gas and fæces.

Eighth step: The execum is scarified and anchored to the abdominal wall by through and through silk sutures, which are tied over pieces of rubber tubing (Fig. 2, C) or by chromicized catgut stitches which include the peritonæum and fascia. The wound in the abdomen is closed by the layer method, after which the catheters are stitched to the skin, or preferably retained in place by a narrow strip of adhesive plaster placed between them and attached to the skin (Fig. 2, A).

Ninth step: Cravat clamps (Fig. 2) are adjusted to the ends of the catheters to prevent leakage, after which the operation is completed by applying the ordinary dry dressings, which are held in place by adhesive strips.

Remarks. One catheter should project further than the other, or they should be identified in some other way, in order that the nurse may know which is in the large and which is in the small intestine when the time for irrigation arrives. In order to avoid the danger of infecting the wound the treat-

ments are not begun until the fifth day, unless there is some special reason for doing so. Any of the irrigating solutions recommended in the nonoperatire treatment of colitis may be used for irrigating the small and large bowel after this operation.

In order to avoid irritation to the bowel and skin it is advisable to occasionally change the catheters. This is done by cutting the adhesive strip holding them together (Fig. 2, B) and withdrawing the one projecting into the colon. The Gant catheter guide is then passed over the other and into the small intestine, where it is held until the old catheter has been removed and a new one inserted, when it is withdrawn.

A short piece of tubing is next introduced into the cæcum and bound with adhesive to the catheter entering the small bowel, and then both are prevented from slipping out by a second adhesive strip

applied as described.

Before finally deciding upon the technique as described, I attempted small intestinal irrigation by passing a silver catheter through the cæcal opening and the ileocæcal valve each time the small bowel was irrigated, to avoid the use of two catheters, but this practice was abandoned as impractical because of the difficulty encountered in locating and passing the valve, and further because the patient cannot carry out this form of irrigation.

After recovery, when spontaneous healing does not follow withdrawal of the catheters, the opening may be closed by cauterization or with sutures without general anæsthesia or the necessity of enter-

ing the peritoneal cavity.

This procedure is also useful in the treatment of conditions other than diarrhoea. It may be emploved to advantage in the treatment of ordinary and pernicious anæmia, autointoxication, ptomaine poisoning, diarrhœa of children, intestinal feeding following operations on the mouth, throat, œsophagus, or stomach, in stricture of the œsophagus or stomach, and gastric ulcer, cancer, or other disturbances of the stomach, where rest is indicated, and also can be used for studying different diseases, to note the amount and character of the intestinal juices and discharges, the nature of the fæces, the effect of direct action of the salines and other cathartics upon the bowel, the results of hot and cold enteroclysis on the blood pressure, and many other interesting problems.

43 WEST FIFTY-SECOND STREET.

THE USE OF THE BRONCHOSCOPE, ŒSOPHA-GOSCOPE, AND GASTROSCOPE.

With Reports of Fourteen Cases.*

BY T. H. HALSTED, M. D., Syracuse, N. Y.,

Professor of Larvingel gy and Ohology, Syracuse University, Medical Department.

So recent and so valuable is the art of bronchoscopy, œsophagoscopy, and gastroscopy that it seemed to the writer that a report, necessarily brief. of the work which he has done along these lines should be of value, because at this stage of development the cumulative experience of various workers will be helpful, in suggesting at least, to what extent

*Read at the meeting of the American Laryngological Association held in Montreal, Can., May (1, 12, 13, 1908)

this method can be applied with safety and benefit. There will be no reference in this paper to the history of the development of this art, though it may be pertinent to say that a number of men in this country, especially Coolidge, Ingals, Mosher, Mayer, Einhorn, Jackson, and Boyce, have done most valuable work, much of it original, in bringing this method to its present state of practical utility.

The work described and cases reported in this paper covers a period of but seven months, and includes eighteen operations on fourteen patients, fourteen times under general anæsthesia, three times under cocaine, once without any anæsthetic. These eighteen operations were all done either as a means of treatment or of diagnosis, and do not include four cesophagoscopies on four young and willing physicians under cocaine, made for experimental purposes, nor a number of direct laryngoscopical examinations made in the office for the purpose of diagnosis as well as to acquire skill in technique. Other experimental and exceedingly valuable work has been on the dog, usually in association with Professor Knowlton, of the physiological department of Syracuse Medical College, and once, the most valuable experience of all, under the direction and instruction of the master of this art in America, Dr. Chevalier Jackson, and his assistant, Dr. Boyce, to whom I cannot sufficiently express my deep sense of gratitude for and appreciation of their generous instruction. I have been assisted in my operations mainly by Dr. J. C. Palmer and Dr. Adelaide Dutcher, and by Dr. J. J. Buettner as anæsthetist. Assistants should be specially trained, as the proper performance of their work is essential to a good result, and I have been fortunate in having good assistants.

The instruments which I have used are those known as Jackson's, having the light at the distal end of the tube, the current supplied by a double dry cell battery, though in the last two cases a transformer, using the city alternating current, was employed. Jackson's instruments, which I have, consist of the separable speculum or spatula, for direct laryngoscopy, two bronchoscopical tubes of 5 and 7 mm. in diameter for upper bronchoscopy, two tracheoscopes for tracheoscopy and lower bronchoscopy, two esophagoscopes, of 7 and 10 mm. in diameter, and one gastroscope, 10 mm. by 80 cm. in length, for the examination of the stomach. The small lamp, no larger than a grain of wheat, has given me surprisingly little trouble, and the blurring of the light by mucus and secretions covering it is easily cleared by the use of the suction pump, swabbing, or the removal of the light carrier and wiping of the lamp, this latter procedure requiring but a fraction of a minute. Among the many advantages of Jackson's instruments over Killian's, in which the light is thrown from the outside down the tube, is the fact that physicians other than the operator car look down the tube and note the findings as well as

the operator himself.

Accessory instruments, consisting of probes. hooks, cannula forceps of various lengths, Mosher's alligator forceps, Coolidge's gauze sponge carriers, suction pump and suction cannulas for removal of fluids and secretions, are necessary. For special cases I had made for myself a spud or he like

curette, used in my first case, a very long galvanocautery electrode, intended to be used in a case of specific web stricture of the larynx. There is a demand, rapidly being met, for a new and complete armamentarium of straight instruments to meet the various conditions that are being encountered.

The general anæsthetic used in most cases was ether, usually preceded by somnoform and atropine to lessen bronchial secretions. While probably, in certain cases, cocaine might be sufficient, yet in æsophagoscopy and gastroscopy the retching against the rigid tube might be disastrous locally by producing perforation, or rupture of a cerebral blood vessel. In the case of a physician on whom I did æsophagoscopy under cocaine, there was produced subconjunctival hæmorrhages through the violent retching. Cocaine is sufficient for direct larvngoscopy in most cases, but in some cases, especially operative, ether is preferable.

Ether was used in all cases where upper bronchoscopy was done, excepting once, when I did it quite satisfactorily under cocaine, and have no doubt it will often be sufficient, as indeed Killian and others have repeatedly shown. In the one case in which I examined the bronchus under cocaine, I had previously examined the same patient under ether and consequently knew what to look for. In her case the ether examination was much the most satisfactory. Rectal anæsthesia should here be the ideal method, but I have had no experience with it.

The patient, excepting for direct laryngoscopy under cocaine, is placed on the back on the table with shoulders projecting and head hanging over and supported in the Boyce position. The correct position of the head and its proper holding are absolutely essential to the proper introduction of the instrument, and an assistant must be trained to do this. In some cases the mouth is best gagged with a tailor's thimble on the assistant's index finger, introduced between the teeth on the left side. In many cases too wide gagging of the mouth interferes seriously with breathing, and in many cases the gag is best dispensed with, but to protect the thin tubular instrument from being bitten and dented, the thimble at least should be constantly held between the teeth. Ferguson's mouth gag was the one used when a gag was employed.

In one case of bronchoscopy, during the act of freeing the bronchus from a plug of mucus, the small gauze sponge became detached from the carrier and was left in the bronchus until a forceps quickly introduced removed it. Since that accident. all sponges have had long white threads attached, the thread wrapped loosely around the carrier. So delicate and so long are the forceps and cotton carriers that the utmost care must be exercised to see that the forceps jaws are properly tempered. Several of mine have been broken while being handled, fortunately not while inside the patient. In working on the larynx or bronchus, one should have instruments ready for an immediate tracheotomy.

While all the cases were of great interest to the writer and all of them warrant an extended report, yet to give a minute report of all would occupy too much time and space. The majority will be given simply in brief outline, some in greater detail. Cases I to VI sen reported at the naceting of the Medical Society of the State of New York in January,

CASE I.—(Esophagoscopy. (Ether.)

Penny Indged for tour and one half years at the cardiac end of the asophagus, in a five year old boy. Obstruction always supposed to be due to congenital stricture. X ray examination revealed forcign body. Operation under fluroscope unsuccessful. Successful removal of penny by

asophagoscopy under ether. Recovery.

Donald C., aged five years, residing in Cortland, N. Y.,
was brought to me by his parents on October 11, 1907, to
have bougies passed to dilate a stricture of the cosophagus which he was supposed to have had from birth. He had considerable difficulty from birth in keeping down milk, and had never taken into the stomach solid food, this always being regurgitated. Between six months and two years of age he had two or three attacks of bronchitis, and wheezed a great deal of the time, the doctor regarding it as asthma. At two years he had a severe attack of dysenas astima. At two years he had a severe attack of dysen-tery. The following winter he coughed and whezeed a great deal, chest filling up when he ate, and relieved on regurgitating his food. At about two and one half years he began having severe pain in the stomach, at times lasting several hours. Months would elapse without these attacks, and again they would continue for several weeks. Had been treated for stomach trouble up to this time.

One consultant said there was a narrowing of the pyloric end of the stomach and suggested gastrojejunostomy. When four years of age he could tell about his swallowing, knowing as soon as he swallowed whether or not the food would be kept down or regurgitated. He could retain liquids, provided he drank them before eating any semi-solid food. Sometimes he would go two or three days without retaining even a drink of water; perhaps he would throw up a piece of food he had eaten several days previous, when he would get relief and could drink nearly a quart of milk, or other liquid. He was constantly hungry, asking at times every five minutes for something to eat. A few weeks before bringing the boy to me the parents had taken him to a well known physician in Buffalo, who made a very careful examination of him, including a chemical examination of the regurgitated food, which he said had not entered the stomach, but had been evidently retained in a pouch. His diagnosis was a congenital stricture of the a pouch. His diagnosis was a congenital stricture of the escophagus, and advised that he be placed in the care of a laryngologist for the passage of esophageal bougies, which was the reason for his being brought to me. A congenital stricture, or narrowing of the esophagus, near the cardiac end of the stomach, had been the almost unanimous diagnosis of the greater number of physicians who attended him or who saw him in consultation at home or in neighboring cities

He was undersized, rather listless and peevish, but in fairly good flesh, teeth so badly decayed that he was practically toothless, nothing abnormal about the throat. gave him a graham cracker, which he readily ate with half a glass of water, and at once began to wheeze. Within two or three minutes he asked for a basin, when the food was regurgitated, not vomited, and the wheezing ceased.

My diagnosis was a stricture at the lower end of the œsophagus with a dilatation or pouch above it, and advised that a radiograph be taken after bismuth and milk had been swallowed, in order to localize if possible the stricture and dilatation. That afternoon Dr. C. E. Coon made an examination with the x ray, after having given him four ounces of milk containing one ounce each of bismuth subnitrate and gum acacia.

On developing the plate, a round body the size of a ten cent piece or penny was revealed opposite the fourth of nfth dorsal vertebræ. The parents were apprised of this, and they returned with the child on October 16th (five days later), when a lateral exposure was made to make sure the foreign body was a round flat body and not a spherical one, such as a marble. This skiagraph showed it to be a flat body, apparently lying in or against the posterior wall of the gullet

The child was put under ether, and under the guidance of the throcope I introduced into the ecophagus a leng Mosher's alligator forceps encased in a soft rubber tubing. the child being in the recumbent position with down hang-ing head. The fluroscope showed plainly the progress of the forceps, and when it reached the foreign body the tub-ing war pulled off, leaving the jaws of the forceps free

The distance from the teeth to the coin was eight and one half inches, or about one inch from the cardiac end of the The forceps was opened when down to the coin, but notwithstanding repeated attempts carefully made, the foreign body could neither be grasped nor felt. We concluded, as we had at first feared might be the case, that cluded, as we had at first feared might be the case, that the coin was probably encysted in the posterior wall of the cesophagus. The child remained one night at the hospital, and the next morning returned home in good condition. I now ordered a set of Jackson's œsophagoscopes and bronchscopes, and during the next three weeks familiarized myself with their use as well as I could. **Casophagoscopy.**—On November 6th the child entered the Women's and Children's Hospital. No food the lightly wars allowed for eighteen house write to the

or liquids were allowed for eighteen hours prior to the operation. Atropine 1/150 grain, was given, and ether adoperation. All opine 1/150 grain, was given, and cutief arministered by Dr. J. J. Buettner. I was assisted by Dr. Dutcher, Dr. Bogart, and Dr. Coon. The child was placed in the dorsal position with head hanging down over the table, mouth held open with the Ferguson mouth gag. The table, mouth held open with the Ferguson mouth gag. esophagoscope, 40 cm. long by 7 mm., was then intro-duced and a careful inspection of the gullet made, gradually extending the tube downward toward the cardia. wall of the esophagus, pinkish in color, was beautifully

t.—Case I Skingraph showing penny Lodged at cardiac end of es phages in a rive year old child. Foreign body present tout and a half years. The Röntgen tube, because of its position, has the win the shadow higher than its actual situation.

illuminated, and at the lower end, about seven inches from the teeth, entered a distinctly enlarged cavity

After more than an hour's searching and using the probe to feel any metallic substance, but without result, I introduced through the tube a right angle curette or spud like in-strument which I had had made for the purpose, and gently curetted or scrapei the posterior wall of the œsophagus at a distance of about eight and one half inches from the teeth, corresponding with the location we had made on the previous fluroscopic examination. This was done very gently and carefully. On removing the spud and drying the surface of the few drops of blood, the edge of the coin was clearly seen. The long tube forceps was now introduced, and on the second introduction the forceps caught the coin frank and previous representations. caught the coin firmly, and penny, tube, and forceps were all removed together

The boy made an uneventful recovery, not regurgitating any food after the second or third day, though ten days after operation he had an attack of acute indigestion There began at once an improvement in his swallowing which has steadily continued, although now six months since the removal of the foreign body, the food swallowed is sometimes returned without apparently entering the stomach. He has gained greatly in his general condition he cats regularly, and seldom complains of being hungry or wanting food between meals. Whether a permanent stricture at the cardiac end of the stomach will remain, time alone will tell, but it is quite possible that as time goes on the thickening may gradually lessen and disap-

The penny had become absorbed to such an extent that it lost twenty-five per cent. in weight, is thinner than a ten cent piece, not more than two thirds of its normal thickness, and in diameter is midway between a ten cent piece and a penny. It had lodged in the posterior wall of the cardiac end of the osophagus probably when the child was six months old, possibly earlier, and had become imbedded or encysted, and had been there for at least four and a half years. At the rate of absorption that had been going on had the child lived, the penny might have been absorbed in twenty years. The x ray was of the greatest value, in fact, without it, it is probable the cause of the obstruction would not have been revealed, because the esophagoscope failed to discover it until the wall covering it was removed

Case II. Power laryngoscopy and tracherscopy. For eign body, fin of a fish, lodged for two weeks in the traches of an eight months old infant. Direct laryngoscopy, tracheotomy, and tracheoscopy under chloroform. Removal of foreign body.

was called in consultation with Dr. Hotaling on De cember 10th to see this baby, with a view to possible intubation, though Dr. Hotaling felt confident that diphtheria was not the cause of the dyspnæa from which the baby had been suffering for nearly a week. Epigastric and episternal recessions were marked, hoarseness on crying no fever, no pseudomembrane in throat. The dyspnœa was not urgent. After a careful examination, a diagnosis of probable foreign body in larynx or trachea was made The parents were urged to take the child to the Women's and Children's Hospital, which was done. An x ray ex amination by Dr. Coon was negative. A culture was negaamination by Dr. Coon was negative. A culture was nega-tive. Steam inhalations were employed, and gave some relief. On December 12th, two days later, the parents consented to an examination and operation, if necessary,

under general anæsthesia.

Operation: Preparations for an immediate tracheotomy were made. The child was given chloroform, and after much difficulty, because of its age (eight months), its undersize (weighing but fifteen pounds), my own inexperience (this being my first attempt to do a direct laryn-goscopy), a beautiful view of the larynx through the sep-arable speculum was obtained. The cords were seen per-fectly, and beyond the chink of the glottis in the trachea was clearly seen a foreign body, located about an inch below the cords and seemingly attached to the right side of the trachea, looking much like a loose piece of cartilage Several times during the examination the dyspinca became so threatening, the heart so weak, and pulse at times almost imperceptible, that I was on the point of opening the trachea, when the breathing would clear up, and the examination and attempt to remove the foreign body through the mouth continued. I was unable to introduce between the mouth comminded. I was unable to introduce between the cords the smallest bronchoscope, the glottic opening being so small, but introduced both the cannula forceps and Mosher's alligator forceps several times and attempted to grasp the foreign body, but always unsuccessfully. Finally, the breathing suddenly became so bad that I did an immediate tracheotomy, with relief to the dyspnœa, but I could not find the foreign body until the small tracheo-scopic tube was carried through the wound into the wind pipe, when it was discovered and removed, proving to be the fin of a fish. A tracheal cannula was inserted and worn for five days, at the end of which time it was removed, and the wound promptly healed, the child making an un-

CASE III.—Direct laryngoscopy (cther) for removal of papilloma of vocal cords, in a boy, nincteen years old.

Operation successful.

I had previously made a number of unsatisfactory at tempts at removal in the old way, under reflected light and cocaine, and later with direct laryngoscopy under cocaine but the boy had such complete lack of control of himselt that not much could be done

By the direct method under ether the papilloma was re-

moved without any difficulty.

C.se IV.—Œsophagoscopy (ether) in a neurotic girl of fourteen for diagnosis of asophageal obstruction. Spasmodic stricture and all symptoms entirely relieved by the examination.

This girl, who was rather anemic and of a marked neurotic temperament, was referred to me because of in ability to swallow solid food for the previous two months. There was no pain, no history of traumatism. The tonsils were enlarged, and there was a large mass of adenoids present. These were removed with relief to the nasal obstruction, but not to obstructed deglutition. Two months later, diagnosticating the condition as probably a hysterical

two months, and at longer intervals with less severity for

the past eighteen months.

A laryngeoscopical examination showed no laryngeal obstruction, no abductor paralysis, and the trachea as far as could be seen showed no obstruction. The difficulty was apparently at the bifurcation of the trachea, or in the mediastinum. There was a fulness of the right lobe of the thyreoid with distinct pulsation, some dulness over the upper part of the chest on both sides in front. No bruit could be detected. The diagnosis of mediastinal pressure upon the lower end of the trachea or bronchi was made, and she was sent to St. Joseph's Hospital for further observation and care. Here she came under the care of Dr. Elsner on the medical side and of myself. Dr. Coon made several skiographs, some of which were unsatisfactory, but he thought he was able to detect a dilatation of the innominate. Dr. Elsner's opinion was that a mediastinal tumor was causing the dyspneae. Inhalations of steam were prescribed every two hours.

A bronchoscopical examination was made under ether on January 18th. The separable speculum was introduced down to the larynx, which was free from obstruction; the bronchoscopical tube was then inserted between the cords, discovering no obstruction here until the bifurcation was reached. At the bifurcation of the trachea, as detected both by the eye and the probe, was a mass of cicatricial tissue which extended into the right bronchus on the right side, and seemingly narrowed the left bronchial opening to a narrow slit, through which the large bronchoscopeal tube could not pass. An inch below the bifurcation in the right bronchus there was a web of cicatricial tissue encircling the circumference of the bronchus and narrowing the calibre of the tube at least a half. The large bronchoscope was removed, and a smaller one inserted and passed through

the narrow opening into the left bronchus.

I was able to demonstrate the bronchial stricture and

I was able to demonstrate the bronchial stricture and the cicatricial tissue at the bifurcation to the eight or ten physicians who were present and who were able to recognize the conditions as clearly as I could. It is possible the left bronchus was narrowed by external pressure as well as by the scar tissue. The diagnosis was syphilitic stricture of both bronchi, with probably some glandular thickening in the mediastinum, which might account for the shadows as shown in the radiograph. I was not aware that I had seen this patient before, but learned at the time of the examination that I had treated her at the dispensary some years previous for some throat affection, the nature of which I had no recollection.

After the examination I looked up the dispensary records and found I had treated her five years ago for syphilitic (tertiary) ulcer on the posterior wall of the nasopharynx, and which had promptly healed under the iodides.

Under mercurial unctions, large doses of the iodides, and inhalations of steam, the patient immediately began to improve, and during the three months she was in the hospital had but one serious and threatening attack of dyspnæa. This was relieved by expelling a large mucilaginous semi-

One month later, under cocaine at my office, with the patient sitting up, upper bronchoscopy was again done, and the strictures again seen. A month later, under ether at the hospital, the patient submitted to a third bronchoscopy, this time with a view to local treatment. The strictures were located as before, the ulcerations covered with a hard scab or crust, exactly like the crusts that form on the anterior part of the nasal septum, were removed by forceps, and a moist gauze sponge and a ten per cent. solution of argyrol applied. There was no reaction, and she left the hospital in two days, and is very mych improved. She is taking 180 grains of potassium iodide daily.

My present plan is to repeat the applications of argyrol under eocaine bronchoscopy, hoping to get rid of the crusts, and when that occurs she will be relieved of her dyspnea almost entirely, and if not dilatation of the stricture will

CASE VII.—Direct laryngoscopy under ether in an eight

months old baby revealed a sharp piece of glass imbedded in largux. Attempt at removal dislodged it, causing its disappearance but not removal. A second operation was refused. Baby in former condition.

The clinical history of this baby, who was a patient of Dr. Werfelman's, was almost exactly that of Case II, and after sensultation a chagnesis of foreign body in the

neurosis, but still uncertain, I advised an desophageal examination. This was done on December 24, 1907, at St Joseph's Hospital, under ether. The desophagus, pale pink in color, with no ulceration, no stenosis, was explored throughout, and nothing that seemed abnormal discovered, beyond a very decided fluttering or thumping, at a point half way down, of the anterior wall of the desophagus against the instrument. This was synchronous with the heart beat, and was visible to the eye and felt against the instrument, and even heard outside the body. On passing this particular point the fluttering stopped. Whether this was an abnormality or of pathological significance I do not know. It is nearly five months since the examination, and the girl has had absolutely no difficulty in swallowing solids as well as liquids since the time of the examination I concluded it was a case of hysterical dysphagia in a highly neurotic young girl, though I dislike to use the term hysterical.

Case V.—Direct larying scopy and upper asophagoscopy

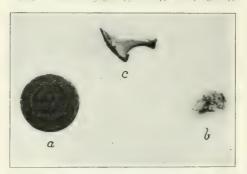

Fig. 2. 2 Some removed from cardiac end of recoplingus (Case I):

b. fin of a fish removed from the trachea of an eight months infant (Case II); c, duck bone removed from right bronchus (Case X).

(cocana) or a girl for suspected foreign body, which was not present but had ben expelled.

An examination was made under cocaine, with the separable speculum, of the larynx, lower pharynx, and upper end of the esophagus of a girl of twenty, giving a history of having swallowed a pin, which she thought was lodged in the throat. An x ray made by Dr. Burch, prior to my examination, was negative. My examination revealed a swelling of the arytenoids, caused possibly by the previous efforts of a physician groping in the dark with forceps to find the pin. The patient remained in the hospital three days, at the end of which time all symptoms and swelling had disappeared.

had disappeared.

CASE VI.—Upper bronchoscopy (ether) for diagnostic purposes. Syphilitic stricture of both bronchi, with ulceration and crusts, rerealed. Second bronchoscopy two months later, under coaine. Third bronchoscopy one month later, under ether, when argyrol was applied directly to the ulcers

in both bronch

I was called on January 10, 1908, in consultation with Dr. Mulherin, to see Mrs. E., aged fifty-five years, because i a desparation of about origin. The appointment was for 3 o'clock, but at I an urgent telephone message came from the family to come as quickly as I could, as the natient was dying. When I reached there I found Dr. Mulherin had preceded me by a few minutes. The patient was recovering from an acute attack of dyspnœa. Her forchead was clammy, covered with cold perspiration, hands cold, lips bluish, and breathing labored but not alarmingly severe, as she was now recovering from what had been a very severe attack of suffocation. The voice was clear. Dr. Mulherin had seen her in several similar attacks during the past year, and said they were relieved by the expulsion by coughing of a dark grayish, thick, and tenacious mucopurulent discharge, the expulsion of which

heat externally, and the swallowing of petrolatum. She

larınx was made. An x ray by Dr. Coon was negative. The child was received at St. Joseph's Hospital and was etherized. With the separable spatula the larynx was brought into view, and both Dr. Werfelman and I recognized to the proper a foreign body, bodying like prices of the proper by the bodying like prices of the prices mized at once a foreign body, looking like a piece of glass about an eighth of an inch long and shaped like the end of a wooden toothpick, lodged in or projecting from the surface of the swollen left arytenoid. There was no mistaking it, and its removal seemed simple, but on attempting to grasp it with the forceps it simply changed position, and notwithstanding several attempts at removal, it finally disappeared from sight, either being dislodged and swallowed or dislodged, entering the lower respiratory tract, or what seemed most probable, disappeared into the soft tissues and became buried. It seemed wisest to desist and await developments. The child was better for a few days, when the same symptoms recurred, and continue. Unfortunately, the parents have changed physicians, and will not allow another operation, hoping that with the advent of warm weather its so called asthma will clear up. I hope, how-

ever, to be able to make another attempt soon.

Case VIII.—This was the removal from a man, aged fifty, of a papilloma from the lower end of the pharynx, at the entrance to the œsophagus, using the separable specu-

lum, and a long Jarvis snare.

Use IX.—Direct laryngoscopy (cocame) for galvanocau tery of syphilitic stricture of the larynx in a woman, Showed impracticability of galvanocautery in this case.

This patient, a woman of fifty, who has been under my care for two years, requiring repeated intubations. I had hoped that I might be able to use the galvanocautery electrode in destroying what had appeared in the laryngeal mirror to be a thin cicatricial web, but, under direct laryngoscopy, what seemed a web was quite a thick, deep mass of cicatricial tissue, too thick to think of using the galvano-Case X.—Under bronchoscopy (ether) removal of a sharp duck bone from the second subdivision of the middle right bronchus. Operation successful.

Mrs. E., of Parish, N. Y., while eating duck at noon din-

ner on March 3d, on taking a deep inspiration while laughing, felt a piece of bone drawn into the throat, choking and greatly alarming her. Attempts at removal were unsuc-cessful, and the bone seemed every minute to be drawn more deeply into the windpipe, and on into the chest. The dyspnœa, which was great at first, gradually subsided. Her physician, Dr. Foote, was sent for, and on his arrival advised her going to Syracuse, and referred her to Dr. S. B. Craton, who saw her five hours later. He sent her to St. Joseph's Hospital, and asked me to take care of her. I saw her at 8 p. m. with Dr. Craton, seven hours after the accident. She was sitting up breathing quietly, no dyspnæa, voice clear, pain on coughing, and a sense of oppression over the middle of the right lung. Since the accident she had coughed up blood, first clear, later mixed with mucus.

On examination with the laryngeal mirror, a distinct scratch was seen on the posterior wall of the pharynx, one vocal cord was reddened and swollen and showed signs of an abrasion, blood in trachea. Auscultation and percussion She was sent to the operating room and etherized. The separable spatula was introduced, and through it the longest bronchoscope was passed between the vocal cords to the bifurcation of the trachea, and finding nothing, the right main bronchus was entered and explored, and nothing being discovered, the upper branch was entered and nothing found. The middle branch was then entered, and at the second subdivision of this branch a white, ivory like foreign body, seemingly the size of the head of a match, was seen. On touching it with the the head of a match, was seen. On touching it with bronchoscope or probe, cough became very severe. pledget of cotton saturated with a five per cent. cocaine solution was carried down, and the parts were soon agesthetized. On the third introduction of the tubular forceps the body was firmly grasped and bronchoscope, forceps, and foreign body were withdrawn together. It proved to be one of the small bones of a duck's leg, somewhat L shaped, not unlike a wish bone, six or eight times larger than it had appeared, because one of the prongs or processes had projected down into one bronchiole, while the other had entered another, and only a small part at the angle of the bone had been presented to the bronchoscope One of the bony processes was facetted and smooth, the

other as sharp as a needle, and this had evidently cut as it went down. A localized bronchitis developed, but cleared up, so that the patient returned home on the fifth day

The next day being Sunday, friends in great numbers visited her, and heard her repeated recitals of her experi-At supper she felt certain that a piece of cake was inhaled and drawn down into the same place in the lung Dr. Foote was called at midnight, and in the morning brought her back to my office. There was no evidence of anything beyond the fact that she was exceedingly nervous and almost hysterical. She was sent to the hospital, where she remained quietly, and with the aid of bromides soon regained her normal condition, and went home in a few days. There has been no further difficulty.

CASE XI.—Gastroscopy (under ether) for diagnosis in recurrent gastric ulcer after a gastrojejunostomy in a woman of fifty years. Marked stricture of the cardia with spasm and cyanosis. Second gastroscopy under ether three weeks later. Hamorrhage caused cessation of operation. Third gastroscopy (ether) two weeks later. Gray scar observed, argyrol applied to reddened inflamed area. Patient greatly

relieved of all symptoms.

Mrs. L., housewife, age fifty, patient of Dr. J. J. Buettner, had been an invalid and entirely incapacitated for work for more than two years. In 1905 she began to vomit blood, and had upwards of one hundred hæmorrhages from the stomach till her entrance to the Women's and Children's Hospital on April 16. 1907. Severe attacks of cyanosis and syncope, accompanied by great pain in the gastric region, were pronounced features of her clinical history. These attacks were so severe that death was frequently thought imminent. They occurred weekly, sometimes daily for months, and several years prior to her entering the hospital. Gastric ulcer was diagnosticated, and gastrojejunostomy performed by Dr. McLennan, in August, 1907. Patient left the hospital greatly improved five weeks Two months after the operation, bloody vomit and pain referred to the site of operation recurred, and she was gradually getting into her former condition when she reentered the hospital, January 27, 1908. Dr. Buettner was anxious to have me use the gastroscope. So bad was her general condition that I refused for several weeks, but finally, on February 27, 1908, she was etherized by Bucttner and the gastroscope passed. There was no difficulty until the cardia was reached and the tube entered the stomach. There was decided stricture or tightness encountered on going through the cardia. Breathing immediately ceased, but resumed as soon as the tube was withdrawn into the œsophagus. The gastroscope was passed into the stomach and soon withdrawn, say in fifteen to twenty seconds (because of breathing ceasing), eight or ten times. The folds and rugæ were seen; no ulcer discovered. She left the operating table in good condition. No vomiting or hæmorrhage followed, and she was so much relieved of all her symptoms that she begged me to again make an examination.

Second gastroscopy under ether on March 12, 1908. There was considerable hæmorrhage at this examination. The complete absence of cardia spasm and of stricture on entering the stomach was noteworthy. Her improvement continued, and again, at her own urgent request, I made a third gastroscopy under ether on April 14, 1908, again noting absence of cardia spasm and stricture. No hæmorrhage, and a splendid view of the stomach wall was obtained. gray scar was observed, and to a small reddened, inflamed area a fifty per cent. solution of argyrol was applied with a cotton carrier. The patient left the hospital three weeks ago (a few days after last operation), and during this time she has been visited but twice by Dr. Buettner, the longest period in three years without medical attendance. She has walked several blocks. There has been no cyanosis since the first gastroscopy. A slight hæmorrhage of blood

at menstrual period.

CASE XII.—Gastroscopy in a girl, of twenty-six years (under ether), with history of gastric ulcer, revealed a scar and an ulcer, and pyloric opening was seen. Argyrol ap-plied to the ulcer. Marked improvement followed.

Miss B., aged twenty-six, patient of Dr. Buettner, servant. In the spring of 1907 first symptoms referable to stomach. In June, 1907, she came under the care of Dr. Buettner, who diagnosticated ulcer of the stomach, and had treated her for it since that time. In October, 1907, she entered the Women's and Children's Hospital, remaining under treatment one anoath, when she left improved. In Lamary, 1008, she became much worse, and gave up work in February. Vomited blood, and blood in stools almost daily. On March 6, 1908, she entered the Women's and Children's Hospital for the purpose of having an experimental contents of the content and Children's Hospital for the purpose of having an examination of the stomach with the gastroscope. On March 7th, under deep ether anæsthesia, the gastroscope was introduced, and gradually passed down the œsophagus, which was pale in color, until the cardia was reached and entered. The stomach wall was thoroughly and systematically examined the present of the product of the pr plored, the rugæ folding and unfolding as the instrument passed over the wall, giving many and varied pictures. The pyloric opening was seen and the duodenum itself viewed for perhaps an inch in depth. A grayish patch, oblong and half an inch in length, was seen on the stomach wall. It was apparently a scar. A reddened and inflamed area of about the same size was localized and thought to be an ulcer. A fifty same size was nocalized and thought to be an unet. A may per cent. solution of argyrol was applied by means of a cotton carrier to this. She recovered from the ether with no unpleasant or untoward symptoms following, and left the hospital two days later. Since then, two months, there has been no return of symptoms, and she feels better than she has at any time during the past two years.

Case XIII.—Asphyxia in a new born infant, caused by pressure of cularged thyreoid and thymus glands. Direct laryngoscopy and passage of long cannula into the trachea and bronchus giving temporary relief and prolonging life sixteen hours. Intubation. Death. Autopsy.

On April 13, 1908, at 2 p. m., I was called by Dr. George B. Broad to St. Joseph's Hospital to do a tracheotomy on a child just delivered by him. When I reached the hospital the child was two hours old, almost asphyxiated, blue, and kept alive only as the father breathed deeply into the child's mouth. When he stopped the breathing ceased. The usual methods employed in resuscitating new born babies had been employed before I arrived.

Dr. Broad was about to do a tracheotomy as I entered the room. The child's pulse was scarcely perceptible. The heart was apparently normal. The child had never cried or taken a deep inspiration. On examination it was seen to be a large, plump baby, weighing about ten pounds, face and neck a deep blue, puffed and swollen, veins distended, and a large mass, apparently an enormously enlarged thyand a large mass, apparently an enormously enlarged truy-recoid gland covered by a large plexus of veins, was easily felt covering the anterior part of the neck, extending from the thyreoid cartilage to the sternum. The mass was long-est in the transverse diameter. A tracheotomy would ne-cessitate going through this mass and would surely be immediately fatal in the child's condition. On passing the finger into the mouth to palpate the entrance to the larynx, the sensation to the finger was that there was no orifice, suggesting a partial atresia of the larynx. The father kept the child alive by continuing to breathe into it while I prepared for a direct examination of the larynx. On introducing the spatula beyond the epiglottis and elevating it for ducing the spatula beyond the epiglottis and elevating it for inspection of the larynx, the child took its first unaided inspiration. The larynx was normal, the miniature vocal cords and chink of the glottis with trachea beyond showed up perfectly. I have never seen the interior of the larynx more clearly in adult or child. Respiration now became regular and the color began to improve. As soon as the spatula was removed asphysia returned. An attempt to introduce the smallest bronchoscope was made but failed, because it was too large. A one year O'Dwyer intubation tube was introduced through the speculum and gave such tube was introduced through the speculum and gave such relief for half an hour that the child's lips became red and it breathed regularly, but at the end of half an hour it suddenly became worse, and the tube was withdrawn, and the long straight suction cannula was passed into the trachea and bronchus, an enlarged thymus pressing on the trachea and bronchus being now suspected, in addition to the enlarged thyroid gland. This relieved the cyanosis for a time. The suction pump to withdraw any secretion in the tube was used, but without result. A soft rubber catheter was passed through the mouth into the trachea and gave some relief. At the end of four hours of this work the breathing was regular, though very superficial, and the child's lips and face were red and had entirely on the neck. We left the hospital at 7 o'clock, with instructions to keep the head extended. The child's condition of the light of the condition of the light of the light of the child's condition in the light of suddenly became worse, and the tube was withdrawn, and werting a tracheotomy, thymectomy, considering the large veins and glands that the transition of the transition med by the transition of the manner, when the

breathing improved, only to have another failure at 4 a. m.,

sixteen hours later, when it died.

Autopsy: Autopsy was made by Dr. Broad. The baby, a girl, was very well developed and nourished, weighing about ten pounds. A mass consisting of thyreoid tissue palpable in the middle of the neck and extending from the thyreoid cartilage to the uper border of the sternum. There thyreod cartilage to the uper border of the sternum. There were many large veins in and about the mass. The chest was then opened, and the relationship of the trachea to the surrounding structures observed. So far as could be determined there was no great pressure on the trachea or compression of it. The thymus gland covered the whole front of the trachea just below the upper border of the sternum and extending downward for about two inches. Fach loke was from two to two and a quarter inches long. Each lobe was from two to two and a quarter inches long, They were about one half inch in thickness at the upper part, much thinner below, apparently large but normal in contour. The trachea with the larynx was removed, but on abnormality or defect was observed in either structure. Both lungs contained air. The foramen ovale was open, otherwise the heart was normal. The structure of every organ with the exception of the thymus, both in the thorax and abdomen, seemed normal. The cranium was not opened.

CASE XIV.—Esophagoscopy and bronchoscopy in a woman, seventy years of age. Stricture of asophagus due to new growth. Pouch or dilatation, with well marked rugæ in the walls. Bougie passed through instrument and

on through the stricture.

Mrs. K., age seventy years, large woman, weighing 100 pounds, was seen by me in consultation with her physician, Dr. Dwinelle, in January, 1908. She had been unable to swallow and retain any solid food for two years, with a history of regurgitating food beginning sixteen years ago, and for two years combably sevents. and for two years constantly present and getting worse. Has wheezed after eating, more or less all of this time. No pain, no history of hæmorrhage. A diagnosis of stricture of the esophagus, with dilatation or pouch above it, was made, and a radiograph and œsophagoscopical examwas made, and a radiograph and esophagoscopical examination advised. A radiograph made by Dr. Coon showed distinctly a pouch of the esophagus. On May 1, 1908, at the Women's and Children's Hospital, I made an examination of the esophagus and bronchus. The large sized esophagoscope was passed down the gullet to a point nine inches from the teeth, when it entered a pouch or dilatation two inches in length, and containing some remnants of food which were removed with forces. The wall of this food, which were removed with forceps. The wall of this pouch was exactly like that of the stomach as seen in other cases, showing the same rugæ and folds, excepting that it was paler. At the bottom of the pouch the tube came up against the obstruction. This was caused by an infiltration against the obstruction. This was caused by an infiltration of the posterior and left lateral wall of the cesophagus, hard and firm to the probe; to the eye it seemed distinctly papillated. A number 12 hard rubber olive tipped bougie was, with difficulty, passed down through the stricture, which was exceedingly tight and narrow, and apparently two inches in length. Two small pieces of the wall were removed with forceps and reported by Dr. Steensland, the pathologist to be simply squarous enithelium. The obpathologist, to be simply squamous epithelium. The obstruction was evidently due to a tumor, probably carcinoma, in the mediastinum and involving the wall of the œsophagus. The trachea and bronchus were examined with the bronchoscope, but nothing adventitious discovered

Recapitulation. Eighteen operations or examinations were performed upon fourteen patients, fourteen times under general anæsthesia (ether in all but one), three under cocaine, and one without any anæsthetic. The age of the patients varied from a new born babe of two hours to an elderly woman of seventy years. In four cases the operations were for the removal of foreign bodies; a penny in the œsophagus of a five year old boy, a bone in the bronchus of a woman, a fish fin in the trachea of an eight months' infant, a spicula of glass in the larynx of an eight months' infant, all being removed but the

Of the remaining cases, operations and examinations were for papilloma of the larynx, stricture of larynx, papilloma of lower pharynx, stricture (spasmodic) and structure (organic) of the œsophagus, suspected foreign body in the œsophagus, three times on one patient for stricture and ulceration of the bronchus, once for relief of asphyxia in new born infant caused by pressure of enlarged thyreoid and thymus glands, and four times for examination of the stomach for gastric ulcer or other lesion.

Experimental work on the dog to determine the cause of the inhibition of respiration on the passage of the gastroscope from the œsophagus to the stomach, and of the introduction of the bronchoscope into the bronchus, was made in conjunction with Dr. Frank P. Knowlton, professor of physiology. This was suggested because of the marked effect on respiration observed in the passage of the gastroscope into the stomach, noted in Case XI, the same effect also being observed while working on a dog.

Professor Knowlton reports the result of the ex-

periment as follows:

| permitted to the control of the cont | | | | |
|--|--|---|--|--|
| Light anæsthesia. | Rate per minute of respirations, | Remarks. | | |

"The inhibition of respiration," he adds, "is apparently due to reflex effect on the respiratory centre, arising from irritation of the gastric mucous membrane, the vagus nerves being afferent pathways. A similar effect has been noted in the rabbit, and further experiments are being carried out."

It would seem from this experiment that in passing the gastroscope through the cardia no danger need be feared from this reflex irritation, which could be overcome in any given case by the application of cocaine.

Conclusion.—Direct visual examination of the larynx, the trachea, and the bronchus, down almost to the last subdivision of the bronchiole, is a practical thing and of inestimable value, not alone for the removal of foreign bodies in the lower air passages, but for the diagnosis and local treatment, both by topical applications and surgical interference, of various lesions that affect the larynx. trachea, bronchus, and the lung, such as laryngeal tumors, tracheal and bronchial ulcers, tuberculous or other lesions, and lung abscesses, discovering the cause and location of pressure on the trachea and bronchus.

By means of œsophagoscopy the accurate diagnosis and treatment of many hitherto inaccessible diseases of the gullet becomes possible. The causes of painful and difficult deglutition, the ætiology and diagnosis and localization of œsophageal obstructions and stricture will depend not so much upon the findings of the bougie as upon the observations of the eye, aided by the probe.

Thanks to the brilliant work of Chevalier Jackson, the stomach has been added to the list of internal organs capable of being examined directly by the eye. Through the gastroscope he has demonstrated the possibility of making a systematic and complete examination of from two thirds to three fourths of the stomach wall; that in many cases the pylorus can be seen and probed; that gastric ulcers can be treated locally; that early diagnosis of carcinoma can be made; that sections of tumors can be removed for microscopical examination—in a word, that the stomach, like the larynx, is subject to direct and local examination and treatment.

831 UNIVERSITY BLOCK.

AN EXTENSION, WITHOUT USE OF WEIGHTS, FOR FRACTURES.

Illustrated in Fracture of the Neck et the Fewur - An Las: Method of Applying Dressings, Especially to the Lower Limb.

By Charles M. Paul, M. D., Cincinnati.

Plaster dressings upon the lower extremity are difficult of application without some means by which the need of lifting the part for the turns may be done away with. Herewith is shown an apparatus for easy application of plaster (or other) dressing to the hip, thigh, leg, pelvis, or spine (Fig. 1). It consists of an ordinary Bradford

Fig. 1 - Application of iron strip for extension,

frame, covered with a bag of strong, unbleached muslin. A third layer of outing flannel or lint is placed upon this, and fastened at the edge, with pins, to the muslin. Patient is now placed upon this, and the ends of the frame rested upon two chairs or tables. A sharp knife now cuts the muslin to form

Fig. .-Pia ter cast split and iming start.

a series of hammocks, as in Fig. I. This enables one to make circular turns without handling any part of patient. Any padding desired at any point may now be placed. Of course, parts of the muslin are included in any dressing, and so remain, therefore the use of the lint or outing flannel. Its use

is demonstrated in the further illustrations of an extension dressing, without weights, applied as for a fracture of neck of femur.

An adhesive stirrup extension is applied, gripping only as far as the knee. An outing flannel roller is now applied to cover the thigh and abdomen to rib edge (Fig. 2). This primary protective dressing holds in place a padding of *felt* placed over the groin so that the upper edge of the plaster applied may have no chance to infringe on the flesh at this point.

A weight may now be applied to the stirrup to keep up extension during the further application of the dressing or kept up by an assistant.

Plaster of Paris is now applied, following the extent of the protective dressing until about half the intended thickness of plaster is applied. An iron strip reaching from about lower end of upper third

Unc. 3 Completed dressing for fracture of hip or thigh,

of the thigh, inner and outer, and bent at bottom, as shown in Fig. 2, is now placed in position, before the plaster is dry. This strip extends about 6 inches below the bottom of the foot. Its size is one-half inch by one-eighth inch. This iron strip is now covered with plaster, repeating the turns made by the protective and porous plaster dressing until a strong cast is made. After this has been allowed to harden thoroughly, a few turns of soft rubber tubing are now made between the stirrup and the iron frame, a small piece of wood being used to keep the adhesive from pressing on the malleoli, as in Figs. 3 and 4. After completing the dressing to this point, an outing flannel bandage is now placed to include the leg, stirrup, iron rod, and foot, from below knee down. Over this is placed a light plaster of Preris dressing to from a splint for the leg and

 $P = \{ x \in \mathcal{F} \mid x \in \mathcal{F} \mid x \in \mathcal{F} \text{ to a } x \text{ tope and adhesive} \}$

to keep the foot in proper position. After this is allowed to harden, the patient is lifted into bed a full of the transact, and the muslim cut away at its function with dressings.

If the All somethic entring and lacing of the tart table place

The rubber extension finds its counterextension (through the iron rods) at the upper part of cast, at the groin. Experiment will show how many turns of elastic are required for a certain weight.

Fr s Brolford frame in use

Approximately, four to six turns of one-fourth inch soft rubber tubing, pulled up to good tension, will give about fifteen pounds extension. It will give slowly and should be changed occasionally. The advantage of the extension is evident when notice is called to the fact that any handling of the patient cannot interfere with its continued action. If patient is placed on a Bradford frame, covered with two bags, lacking about 4 inches of meeting at the middle, he can now be handled easily for purposes of cleanliness, nature's calls, to change bedding, etc., etc. He may be carried about on same. All of this without bothering about any weights. Its use for five years has proved very satisfactory.

19 WEST SEVENTH STREET.

SYPHILIS.*

Its Origin, Cause, and Treatment,

By Goerg Merzbach, M. D., Berlin, Germany.

In calling your attention to the origin, cause, and treatment of syphilis, my excuse is threefold: 1, Syphilis is one of the most common and dreaded of all diseases that afflict mankind; 2, knowledge of it is, just for this reason, of the utmost importance not only to the specialist, but also to the general practitioner; and, 3, that during recent years most important additions to our knowledge of the ætiology and the treatment of syphilis have been made.

While within the last quarter of a century, philosophy, political science, history, philology, literature, and art have all made great advances, the most numerous and pronounced discoveries have been in the realm of so called natural science. Further, of all the numerous branches of natural science, none outranks medicine in the advance which it has made, not only in its theoretical aspect, but especially in its knowledge of the ætiology, the pathology, and the treatment of disease. Marke'l advance has been made even within the few years since the midnight bells amounteed the advent of the twentieth cen-

"Read at the transfer the Arizh A could be I finderch Will belonded, Beetz, German v

tury. In the fundam ntal work of Virchow in pathological anatomy, as in the new teaching of Robert Koch and his disciples concerning bacteria, we saw a new life infusing itself into the old methods of medical science and the buds that formed then are now blossoming, and to-day we begin to see the fruit of the hard labor of the past, results and successes which were never even expected.

There is, however, one disease which, as if it were a stepchild, mother medicine seems to have somewhat ignored. This disease is syphilis, which the world has known for five hundred years. The neglect, however, has been that rather of intensity than of kind, for all through the centuries much experimentation has been done, but the ætiology of it has been so obscure, and, consequently, investigation so misdirected and fruitless that much of the work that otherwise might have yielded lasting results has been also without results on account of lack of enthusiasm in the researches.

From the opening years of the present decade, however, a promise of better things has come. Light has recently been shed upon the origin of this disease, while its exciting cause may be considered now established, and, what is of more importance, marked progress has been made in the treatment of syphilis. It is then to these three points that I would

ask your attention at this time.

First, then, in considering the origin of syphilis, we enter an interesting field of the history of medicine. The history of syphilis has occupied the minds of many medical historians, the results of whose researches are embodied in numerous volumes. Although the majority of these works are carefully compiled and exhibit much learning, the most satisfactory tracing of the geographical source of syphilis was left for Dr. Iwan Bloch, a Berlin physician, possessed of astonishing industry, profound sagacity, and sound judgment in the study of origins. These qualities, in conjunction with an extraordinarily broad and deep general knowledge, eminently fitted him for his task.

Bloch, then, whose previous researches into venereal diseases and into the history and social bearings of sexual relations have made his name well known, entered upon his study of the origin of syphilis, having fully digested the material collected by his predecessors, and with a mental tenacity and thoroughness exceptional for even a German. He accomplished his task. To him, then, as the successful pioneer in a region unsuccessfully explored by others, belongs the prize. In his work in two volumes, entitled On the Origin of Syphilis, conceived on a large scale, and filled full of valuable facts, we have at last, to the satisfaction of the medical world, reliable statements as to the source of this disease, truth indeed which even Rosenbaum, in his celebrated History of Syphilis, was not able to fathom.

I shall shortly review the train of thought and the power of research peculiar to this investigator. Voltaire's ironic witticism in the Candide, in which he questions the possibility of tracing the genealogy of syphilis, has lost to-day its meaning, and the famous question of Ricord, "Whence came syphilis and from whom had it origin?" at last has been answered.

Near the close of the fifteenth century syphilis fell upon sunny Italy like a flash of lightning out of a clear sky, striking terror into old and young, rich and poor. Like the plague and leprosy, with which two affections it was at first confounded, it gave ito opportunity of escape.

With the aid of the splendid historical pictures which the pens of Gregorovius, von Muetz, and Leopold von Rancke delineate, let us bring before our minds the political situation in Europe at the time when syphilis first made its appearance on that con-

tinent.

Charles VIII of France had inherited from his father, Louis XI, the rights of the Angevin princes to the principality of Naples. His father had been wise enough not to press the claim, but Charles, vielding to an ambition to be a second Alexander the Great or a Charlemagne, crossed the Alps and descended into Italy for conquest and the assertion of his rights. His army consisted of about 32,000 men of different nationalities, of which 6,000 were Swiss, 10,000 Northern Francs and Dutch, and 5,000 Gascons, also a large number of Spaniards. Furthermore, 800 women, of whom 500 were prostitutes, accompanied this army. With these forces Charles VIII crossed the Italian frontier on the 1st of September, 1494, and as early as the 8th of September a division under the command of the Duke of Orleans engaged a force of about 3,000 Neapolitans and Spaniards at Rapallo, about fourteen miles to the east of Genoa. Completely routing this Italian band, Charles continued his march unhindered to Rome and Naples, after he had made, on November 17th, an alliance with Florence. On the last day of 1494 the French army occupied the Eternal City, then under the rule of Alexander VI, of the famous House of Borgia. Charles and his army remained in Rome throughout January, 1495. During the march from the north the soldiers had indulged in the freest intercourse with not only prostitutes, but also the other women of Italy, and now at Rome gave themselves up to a life of licentiousness. At that time Rome had a large population of prostitutes, the Spanish wantons choosing it as especially favorable for their activities. Delicado a Spaniard, writing at this time, estimated the number of Spanish prostitutes then in Rome to be about 14,000.

The French King finally left Rome on January 28. 1495, and entered Naples through the Porta Capuana at four o'clock in the afternoon of February 22, 1495. A most enthusiastic reception, especially on the part of the female population, was accorded the soldiers, who, together with Charles, were astonished and elated at their easy triumphal march since they crossed the Alps. Charles was now on the territory he had sought, and with his coronation he had obtained the recognition he desired. But instead of setting his kingdom in order, he and his soldiers vielded to the mild southern climate and the wines of those classic hillsides, and if they had engaged in licentious practice before, now they became steeped in debauchery. The chronicles say that the very first day they were in Naples they excelled in drinking orgies and venereal excesses.

Had Charles given himself to setting his house in order instead of to pleasures only, the history of Italy might have been different. As it was, however, Ludovico Sforza, "The Moor" of Milan, who had invited Charles to his conquest in Italy and aided and abetted him, jealous and fearful of the successes of this French invader, induced the chief powers of Europe to unite with him in cutting off the King's return. Charles heard this too late, made a hasty retreat, and after defeating the assembled troops at a pass in the Apennines finally reached Lyons in safety, whence he had set out. He, however, had left one half of his army as a garrison at Naples. These forces were victorious in many skirmishes with the Neapolitans, but when a Spanish fleet with Ferdinand of Aragon on board appeared in the harbor, the people of Naples welcomed it, and themselves aided in cutting down the French garrison. Those who were not killed fled.

These events, narrated at some length, contain the story of how syphilis first began to spread throughout Europe. Contracted by the soldiers of the army of Charles VIII, they diffused it in all quarters as they dispersed. The pestilence came indeed like an explosion, so sudden and so violent

was the outbreak in all quarters.

The conditions and the indescribable effect which the first appearance of syphilis created in the old world have been plainly and authentically depicted by numerous contemporaries, all of whom speak of this beginning of the pestilence as occurring in the period between February and May, 1495, i. e., the time during which the hirelings of the army of Charles VIII sojourned in Naples. From all their references it is evident that the pestilence was new and unknown, and to them frightful because the rapidly progressing symptoms were decidedly destructive.

We will let a number of contemporary writers, who witnessed the oncoming of this terrible disease and who themselves suffered from its effects, bear

testimony.

The Genoese physician, Cataneus, says: "Morbus monstrosus, nullis ante saeculis visus totoque in orbe terrarum incognitus"; and Heusler, who tenaciously adhered to the belief of the antique origin of syphilis, says in his celebrated work, History of Syphilis: "Many a pestilence has been more devastating, more murderous to the human race, than the lust pestilence, which occurred towards the end of the fifteenth century: but never, without an exception, has a malignant disease or pestilence, a plague or a black death, created such a terrifying impres-

sion, or left such a dread to posterity.'

Franciscus Muraltus, the chronicler, also expresses himself: "As the disease was unknown and no description of it could be found in the old works, as neither Hippocrates, Avicenna, or Galen recommended remedies for it, nor mentioned this disease, it killed countless numbers. The physicians of our time employed remedies according to their own judgment, and popes, kings, princes, margraves, gererals, soldiers, nobles, merchants, and, in fact, all those indulging in sensuality, and others, even theologians of all kinds, were afflicted with this distinguished from the unchaste."

This march and progress of syphilis was horrible.

present day that when regions where syphilis has been unknown are attacked by this infection, the ensuing epidemic possesses a peculiar violence. Pollich cites thousands of convalescents as early as 1499, while Summaripa, an Italian physician, says that no words, no pen is capable of describing the sufferings to which those afflicted by the new discase were subjected; sad, indeed, is the fundamental tone which runs throughout the descriptions of Grunpeck, the first German writer on syphilis, as well as through the unceasing lamentations of Ulrich yon Hutten.

The question now naturally arises, a question which Bloch himself also asks. We have explained the sudden spread of syphilis throughout Europe when once the soldiers of Charles had become infected in central Italy, but in what way may we account for the somewhat sudden appearance of syphilis in the principality of Naples and other parts of the peninsula; in short, whence came syphilis to

Italy:

It may indeed seem surprising that a fact so palpable as the first appearance of syphilis and the place of its origin should be so lost in the course of centuries, particularly when it is remembered that its rise began, not in prehistoric times, but in the fifteenth century, when there was considerable literary and scientific activity. However, positive contemporary statements are wanting, and it remains for the medical historian to seek out and weigh what testimony remains.

Bloch gathers his proofs from three principal sources: First, the reports of Spanish authors, to which Montejo, the Spanish military surgeon, refers in his investigations; and second, the brilliant researches of the American Professor Seler; and third, various communications in the Italian chroni-

cles.

The Spanish author whose works are of especial value is Ruy de Diaz de Isla, who lived from 1462 to 1542, was a physician of repute and in his prime when syphilis first appeared in Europe, and was an eye witness of its beginnings on that continent.

This Diaz de Isla was a physician of Barcelona in 1493 and later a surgeon in Sevilla for ten years. He was also chief physician of All Saints' Hospital in Lisbon, where he gained very valuable experience also as regards syphilis, of which he gives an account in his work, dedicated to King Manuel of Portugal. In the first chapter of this book the origin and introduction of syphilis is plainly and positively proved, which reports are absolutely trustworthy, as Diaz depicts only personal experiences and such facts as were witnessed by himself.

These reports may be briefly mentioned here in addition to Bloch's assertions. They have been supplemented by information received from Oviedo and

substantiated by the works of Las Casas.

He shows that in Española syphilis had existed since primeval times. When Columbus discovered America the Indians already possessed a very complicated yet rationally developed mode of treatment for this disease, of which Diaz de Isla, through writings of the natives, became cognizant in the year 1504. The cure consisted in the use of guajac, and the pama, in confunction with hydrotherapeutic, dietetic, and climatic treatment. The

fact that syphilis existed on the Antilles prior to the advent of Columbus makes its coexistence on the mainland of Central America highly probable, which probability is substantiated by information which has been handed down from that highly cultivated and civilized race, the Aztecs. For the facts we are again indebted to the investigations of Montejo and Seler, and we must not overlook that the practice of medicine among the Aztecs had attained to an advanced state and was highly scientific, so that medicine in the new world may be considered as having reached the same standard as the medical practice of the Greeks in the old world.

The physicians of the Aztecs had adopted anæsthesia in surgery; they understood the suturing of They knew the influence of nourishment on the fœtus, and were fully versed in embryotomy, and, for the purpose of systematic researches, they had instituted collections on a large scale, like to our pathological museums and botanical gardens. We may, therefore, without question credit as true the reports of such experienced physicians as Hermandez and Benarides, who testify to the treatment of syphilis by the Aztecs in accord with their primitive science. They assert that the inhabitants were far better acquainted with the disease than they were. These important facts, together with many minor ones, prove that syphilis was very well known on the mainland of America at that time, and was subjected to expert treatment, considering the period. It is, therefore, easy to understand how syphilis was introduced into Europe, as Spain in Europe was the first country to receive syphilis as a gift, so to speak, from the new world. And in Spain, again, the cities Sevilla and Barcelona, where, after their return, the crew of Columbus sojourned for a time, became local centres of epidemics of syphilis. For these facts we have a witness in Sanarego, who speaks of syphilis raging in Spain as early as 1493. consequently two years before the campaign of Charles VIII, and that it had been imported from the West, i. e., America.

It must now be brought to mind that the popes had given both Naples and Sicily to Charles of Anjou. In 1282 Sicily revolted and was united to the Kingdom of Aragon, a Spanish power, to whom it belonged when Charles V of Spain came to the throne. When, in 1435, the older house of Anjou died out, the King of Aragon conquered Naples, and thus it, too, became a Spanish possession, and it was still in the possession of this Spanish King when Charles VIII of France set forth, and it was, as we said at the beginning of this narrative, in order to oust the King of Aragon and to assert the right of the Angevin princes to the principality of Naples, which right he had inherited from his father, that Charles VIII had entered Italy. see, then, how, when in 1492 and 1493 syphilis was brought to Spain from what is now America, it was carried by the Spanish to their possessions in Italy, in 1493 and 1494, and was communicated by the Neapolitans and other Italians to the soldiers of Charles VIII, in 1494 and 1495, to be by them disseminated over Europe as fast as these scattering forces could carry it.

Finally, in addition to these historical proofs the peculiarly typical appearance of syphilis was sufficient evidence that the disease was new, attacking, as it did, in violent epidemics those countries where it had been unknown, namely, Spain and Italy. In the year 1500 and as early as the beginning of the sixteenth century it appeared in the Far East, in China and Japan, while its entrance even into Africa can be authenticated. Everywhere in the Old World the pestilence found virgin soil; wherever it once started it developed and spread with particular virulence, causing universal consternation and fright. This is evident also from the various names originally given to the pestilence that is, consideration being had only of the places from which it came, as West Indian, Haytian, Japanese or French disease, morbus gallicus, morbus burdigalensis, Franch pox, or el mal de Castilla. At last, in the year 1520, the Italian physician, Hieronimo Fracastoro, wrote a poem on the subject, entitled, "Syphilus, sive morbi gallici libri tres," and thus decided the question of name. Syphilus, a character in the poem, is the name of a shepherd, and Sauvages took this name and introduced the word syphilis into technical use, a term which has been used ever since.

And now let me remind you of a pun made by Krafft-Ebing at the International Congress of Medicine in Moscow, when he referred to the intimate union of all civilization by syphilization. It is all too true that every nation under heaven is now interested in the ætiology and treatment of this disease, and are thus seeking incessantly for means to ameliorate "the bitterness with which," according to Master Ekkehard, "all sexual relationship is mingled." Whether or not we have approached closely the desired goal through investigations into the parasitic nature of the disease remains to be seen from the facts to which, in the second place, I would call your attention.

When, on the 3d of March, 1905. Schaudinn's keenness, after joint investigations with Hoffmann, discovered the Spirocheta pallida in a fresh preparation from a recent syphilitic lesion, an opportunity was offered for the discussion of this subject, such as cannot be compared to anything else in the history of medicine. And, strange as it may seem, scarcely any person of note has offered opposition to the theory that the Spirocheta pallida is the exciting cause of syphilis; whereas, on the other hand, this answer to this most important ætiological question has had numerous supporters in the persons of the best authorities of bacteriology and pathology in all parts of the world.

Unfortunately, Fritz Schaudinn's keenness of perception can no longer aid us; but before his premature death he had the satisfaction of knowing that he had left a discovery to the world and humanity which would remain to his name and that of Hoffmann, in the words of Horace, "monumentum aere perennius."

The problem of the cause of syphilis may now be considered as solved, although a final link in the chain of investigations is necessary to render, according to the demands of modern science, the proof indisputable.

It certainly is a singular coincidence that as early as 1837, H. Donne, the discoverer of the *Trichomonas vaginalis*, alleged that the *Spirochata pallida*,

more exactly the vibrio lineola, was the exciting cause of syphilis. After the investigations of Rille and Hoffmann, though, this spirochæta proved to be the Spirochæta refrigerens, parasite of the surface. This microorganism does not enter into consideration in comparison with the real Spirochæta ballida, any more than the Cytorrhyctes luis of Siegel or Bordet, described in 1903, which, notwithstanding the testimony of Metchnikopf, differ from the real Spirochata pallida in the order of the convolutions. The fortunate solving of this long disputed question is due to the cooperation of the zoologist with the syphilologist, who, under the supervision of Lesser, investigated this experimental chain conjointly, and soon attained a wonderful success. The first publications by Schaudinn and Hoffmann, in May, 1905, were quickly followed by the confirmatory statements of Paaschen, Puschke, Fischer, Metchnikopf, and Roux, to whom Schaudinn had sent preparations taken by himself from unbroken papules of the skin. Later Salmon's discoveries of spirochætæ in the papules of pemphigus, and those of Levaditi in the lungs, liver, and spleen of bicongenital syphilis, were published. In the blood taken from the tip of the finger, Raubitschek detected the existence of the Spirochæta pallida and also in the venous blood, as did also Wolters, later, who was followed by Nöggerath and Stächelin. Ehrmann and Lippschütz found it in acquired syphilis; Roscher in a papule of the toe; Rille and Vackerodt in efflorescences of psoriasis palmaris; Levaditi, Petresco, Siebert, Lewandowski, Hirschberg. Dreyer, and Toepel in congenital lues, as also in tabes. This list of investigators could be lengthened greatly, but at present it is sufficient for us to have called attention to the fact that the Spirocheta pallida is found in all the lesions, recent and of long standing, of acquired as well as of congenital syphilis. And it also is of an importance not to be underestimated that we are able to discover the spirochætæ at a comparatively early stage of a suspicious pimple, and thus are enabled to make an early diagnosis of syphilis, just as it is possible for us in the case of old gummata and in other late manifestations of the disease to determine their spe-

The staining process of Schaudinn after Giemsa in the preparation of slides has proved valuable, and has been enlarged upon by Herxheimer, von Bertarelli, and especially by Levaditi, especially in the modification of the Ramon y Cajal process, which, as the best adapted for the purpose, undoubtedly will retain its precedence among the different methods. By means of these methods, which, naturally, notwithstanding their comparative simplicity, result in many failures for the beginner, all the different organs, syphilitic children and feetuses, placenta and undiral cord, as well as all the products of the numerous kinds of syphilis, have been investigated, so that Hoffmann has the privilege to describe the sum total of the results of modern research in his look which has been lately edited.

It is not not intention to enter upon the various methods of searching for spirochætæ, the examination of fresh slide preparations, or upon the occurrence of this exciting cause of the disease in the man applitus pando to all shall personer the

proof of their existence in the tissues of the body, their occurrence in acquired and congenital syphilis and in experimental syphilis.

The third publication of Schaudinn and Hoffmann, in May, 1905, established the indisputable fact that the *Spirochæta pallida* was the exciting cause of syphilis, which had been sought for so long, a fact especially emphasized by its constant appearance, not only in open syphilitic disease centers, but also by its occurrence in the depth of entirely intact syphilides, as primary affections and papules, in the diseased lymph glands, and in the Although, as Hoffmann sadly resplenic blood. marks, the realization of the final postulate—i. e., the cultivation of the organism and the transmission of the disease by means of this pure culture to another susceptible animal, is still outstanding, we are undoubtedly fully justified, on the strength of the attained results, in acknowledging the spirochæta as the exciting cause of syphilis. That is the second eventful discovery in the realm of syphilis investiga-Since the Spirochæta pallida has been distinguished morphologically from other rather similar spirochætæ, Hoffmann has made the proposal to separate the Spirochæta pallida also in name from the other spirochætæ by calling it triponema, or Spirochæta luis, or syphilis spirochæta, which proposition is likely to be accepted.

The practical significance of this bacteriological discovery is, for the present, the possibility of making an early microscopical diagnosis, and consequently the opportunity of beginning an early therapy, or of clearing up an otherwise uncertain diagnosis, or of making manifest a latent infection.

The significance which the syphilis spirochæta has for the pathologist is illustrated by the fact that my friend Benda has demonstrated its existence in diseases of bloodvessels of syphilitics, as also Buschke-Fischer, Levaditi, and Simmonds, in congenital lues, in macerated fœtuses, placenta, and umbilical cords of fœtuses of syphilitic patients. The teachings of Thalman concerning endotoxines, the poisons of the human body, receive in treponema a substantial support. We have, furthermore, learned from the biology of treponema that syphilis spirochætæ, adhering to the circumference of the diseased centre, begin to grow again and travel to the periphery, which accounts for relapsing roseoles and annular syphilides. Yes, we have now even the proofs that later fully virulent parasites circulate in the blood, and, according to Hoffmann, the supposition is justifiable that months after the first general invasion of the body by these germs new metastatic centres can form in the skin and internal organs.

Hoffmann's attempts to inoculate monkeys with syphilitic blood, to do which I had also tried, together with Lasser and Query, and in which Hoffmann only seems to have been successful in one case with stagnant blood, led him to believe that the syphilis spirochætæ are anaerobic microorganisms, a supposition which later investigations have verified. The Spirochæto huis is able without oxygen not only to retain its vitality, but to remain in a condition to reproduce itself. The question as to whether the syphilisspirochæta is a facultative or an obligatory anærobic parasite must remain undecided for the present. This does not compromise the fact that

great light has been shed on the question of syphilis and made the prognosis of any given case better than it ever was before. For centuries all attempted investigations of syphilis made little or no progress, but now suddenly, as though awakening from magic sleep, research has begun to make rapid strides, and is passing by means of the painstaking work of a few fortunate investigators to the pinnacles of knowledge, along that sure path which Schaudinn and Hoffmann paved by their thorough work.

Such is the degree of progress made up to the present day by syphilology. Naturally it opens up a long perspective for the diagnosis, for the therapy, and for the prophylaxis of the disease. But there are probably many sceptics who will say that the course of this discovery will be the same as that of many others in bacteriology that have preceded it, like the investigations concerning the plague and the tubercle bacillus. They will say the discovery of the Spirochata pallida and its relation to syphilis is made, but there is no result following, nothing practical to grasp, nothing consoling for the general public, for whom we scientists are primarily obliged to labor and whose criticism we must accept.

We hope we may say that the end is not yet and expect that here also the fruits will be richly gathered, but for the present we must content ourselves with the therapeutic progress that has been made independently of the knowldge of the spirochæta and which in its line is destined to attain unusual significance. While in general the treatment of syphilis has followed the same methods it has emploved for years, has gone along the old road, almost the same that it traveled in the time of good Ulrich von Hutten, old methods have been modified and better wavs have been discovered. While antimercurialists still dispute with mercurialists, the latter seem to have the majority on their side. These men, however, who favor the use of mercury have not agreed as to the best method of administering their remedy, some favoring the administration by mouth, some that by inunction, and others the hypodermatic method. Of all these methods until recently none could lay claim to undoubted superiority, but recent experimentation has shed new light on the previous difficulties. As I have called your attention to the advances made in the history of syphilis among mankind, and as I have spoken of the progress in the ætiology of the disease as evinced by the discovery of the Spirochæta pallida in all syphilitic lesions and tissues, so now, in the third place, I would bring to your remembrance the great advance that has been made in the treatment of this disease by means of mercurials.

I need not remind you of how unsuited to private practice is mercurialization by means of inunction with mercurial ointment. While in hospitals like those of Vienna and other parts of Europe it may be a cheap and quick form of treatment, its rendering the body greasy, its soiling the underclothing and the bed linen, the impossibility of concealing its use, all with the consequent disturbance of mode of life and vocation, not to mention possible physical disturbance, as local inflammation of the skin and mucous membrane, not only render persistent treatment difficult, but also frequently preclude any satisfactory treatment at all.

When we attempt to speak of the hypodermic injection of mercurials, not much more can be said in its favor. Whether we use calomel, gray oil, the salicylate or the thymolate of mercury, the procedure is very painful, generally infiltration of the tissues causes the patient pain in whatever position he may be, and destruction of tissue with abscess formation often seriously complicates matters, while the persuading of the patient to continue the treatment under any circumstances is frequently impossible. Of course, we must not forget in the use of these insoluble salts of mercury the danger of a sudden and unexpected distressing or even fatal mercurialization, due to the rapid absorption of mercury that has been stored up somewhere in the body from these salts.

If we consider the use of the bichloride, the imidosuccinate, the formamidate, or the peptonate of mercury, blood serum mercury, sozoiodole mercury, or mercuric arsenate, we must further remember that safe hypodermic doses of these are far too mild to be of certain service. Experience has proved that by the use of even the largest possible doses of these salts, in more than half the number of cases, even when the injections have been continued from five to six weeks, a relapse generally occurs within two months from the cessation of the injections, while during the first two years such relapses are of constant occurrence. I have not mentioned treatment by administering mercury by the mouth because the method and its advantages. and disadvantages are well known.

There is then a considerable unanimity of opinion as to the positive value of mercurials in syphilis, and I may add an absolute unanimity of opinion as to the administration by the mouth being the simplest, most convenient, and otherwise the best mode of exhibition if a form of mercury suitable to such form of administration is obtainable. If we are to obtain the desired end in the treatment of syphilisas far as our knowledge goes to-day, there are certain requirements absolutely essential. From a positive standpoint, large quantities of mercury must be administered, and also we must be able to keep the treatment completely under control. To accomplish this latter end the medicament must be capable of exact dosage and its absorption by the system must be sure and uniform.

From a negative standpoint, the medicament must not be difficult to administer and must be noncorrosive so as not to produce local lesions or colic or diarrhœa. I am glad to say that medical science has made progress in this direction. Overbeck and Gorup-Besanez had proved that of all the organs of the body the liver was the one that retained mercury in any amount the longest as well as in the largest quantities for any given time. They showed that mercury, after it had been once absorbed, penetrated all organs and tissues of the body, but that the liver was particularly what might be called the reservoir for mercury. It was further shown that while mercury is eliminated by the fæces, urine, perspiration, and saliva, the quantity eliminated and the rapidity of elimination are in proportion to the quantity absorbed and the rapidity of absorption, and that the absorbed mercury had the greatest affinity for the liver.
